Dr Farmer, of Onondaga This question was in the hands of the Committee on Medical Economics, and then a year ago was passed over to our committee, where I really did think it belonged and still think it belongs. I think it is an educational matter and also a public health matter I feel that little by little, whether we know it or not, the Committee on Public Health has gradually lost its identity, because one public health activity after another was gradually withdrawn from it. I do not want to advise the delegates how to act, but I would like to advise that they give this matter pretty sober and sound judgment

Dr Thomson, of Kings Kings County is very much interested in this I agree with what Dr Farmer has said. If we in Kings County have had any success in the functioning of our public health committee, it has been because all matters concentrate in the public health committee, and through special committees we function on special subjects I think Dr Farmer has taken a very sound stand.

Dr Leber, of New York I think it is one of the greatest public health measures of the day, and is going to be taken up by the laymen if the medical men do not. I think the committee will have its hands full in working out this problem

Dr Podvin, of the Bronx The idea of the introducers of this resolution is that the success of the Anti Diphtheria campaign we have recently witnessed was due largely to the splendid work done by the special committee appointed for that purpose. A special committee to work along the same lines as that Diphtheria Committee would be conducive to the success of this campaign, and therefore we favor the adoption of this resolution as introduced

The motion was put to a vote and carried.

37 DUES OF INCAPACITATED PHYSICIANS (SEC. 6, 9, 33)

Dr Townsend, of New York Your Committee on New Business B has the honor to report favorably on the resolution introduced by Dr Chalmers suspending annual dues to the Medical Society of the State of New York of members of County Societies who have an incapacitating illness of at least three months, with the provisions outlined in the resolutions

WHEREAS, certain practicing physicians in the State have developed diseases which made it essential for them to give up their practice for a time, and whereas this causes, in the majority of instances, their income to cease and works hardships upon them,

THEREFORE, be it resolved that the State dues of any member shall be suspended by the Medical Society of the State of New York during the time that a member is absent for his health, provided that his County Society makes application for such remission or suspension of dues, accompanied by a statement that the County Society has so suspended his County dues

I move the adoption of this resolution

Motion seconded and carried

38 COST OF MEDICAL CARE. (SEC. 29)

Dr Townsend Your Committee reports favorably on the resolution introduced by Dr Aranow to appoint a committee to study the alleged high cost of medical care and report at the next meeting of the House of Delegates I move the adoption of this resolution

Motion seconded

Dr Aranow, of the Bronx I think if you wait another

46 CHOICE OF PHYSICIAN BY INJURED WORKMAN (SEC. 26)

Dr Kosmak I have another report. The Committee on New Business C has considered the resolution introduced by the Bronx delegation relative to the free choice of physician by an injured employee. Your Chairman finds it necessary to report a divided opinion among the members of the Committee on the subject of this resolution. It was felt by the majority from which the chairman is excluded that, while the injured employee should exercise a choice as to his physician, some inherent right in the matter resides in the employer, and that to grant this privilege exclusively to one party, would constitute an injustice to the other

Your Committee therefore suggests that, for the purpose of obtaining the opinion of the house, an open vote be taken on this resolution by the delegates present.

I move the adoption of this report.

Motion seconded

The Secretary I move an amendment to that resolution, that it be considered at a time that Mr Stryker is here to give us his legal advice.

The amendment was seconded, put to a vote and carried

47 PRIZE ESSAYS

Dr Bidell of Albany You doubtless know there are two prizes given, one to the essayist who writes the best essay or presents material gathered in the best manner on subjects selected by a prize committee.

Your committee states, sir, that in the material sent to us it is the unanimous feeling of this committee no essay has been presented worthy of either prize.

It was moved that the report be accepted. Motion seconded and carried.

48 LIMITING DOSAGE OF ALCOHOL

Dr Chalmers, of Queens Presented the following resolution

Whereas, It has been stated in the public press that the great State of Illinois has through an action in court raised the question of the right of Congress to limit the dosage of spirituous liquor as a therapeutic agent in the treatment of disease, and the said action is now pending before the Supreme Court of the United States

THEREFORE BE IT RESOLVED, That the House of Delegates of the Medical Society of the State of New York at its annual meeting held in Utica on June 3rd, 1929, heartily endorses and approves the action of the said State of Illinois, and,

BE IT FURTHER RESOLVED, That the Secretary of the Medical Society of the State of New York be directed to forward to the Governor of the State of Illinois a copy of this resolution

The Speaker Referred to Reference Committee C. (Report, Sec. 50)

The Speaker Is there anything further under the head of New Business to come before the House of Delegates at this time?

49 COST OF MEDICAL CARE (SECS 29 AND 38)

Dr Phillips, of New York I believe we are all more or less familiar with the fact that there is being carried on in this country a very extensive investigation as to the cost of medical care. It has been referred to several times during the meeting of the House of Delegates, and if my memory serves me one or two resolutions have been introduced on that subject. I believe the work that is being done is largely financed by the American Medical Association. It is an important study It seems to me that in view of the fact you have taken certain actions here today, if you wish any action to augment the action which you have recommended in your House of Delegates today it would be wise for you to instruct your delegation to the House of Delegates of the American Medical Association to take such action in the form of resolutions to be presented to the House of Delegates of the American Medical Association in regard to this subject as might represent the opinion and sentiment of this House of Delegates

Dr Cole, of New York The report to be made by the committee will be a report of progress only They are going to make a preliminary report but they do not expect to have the final report until three or four years from now

Dr Aranow, of the Bronx If the House of Delegates so agree, may I suggest that our delegates be instructed to bring a resolution before the American Medical Association similar to the one passed here tonight.

Motion seconded

Dr Phillips I think Dr Aranow meant to say, and I think he did say, our delegates to the American Medical Association, and put that in this resolution

Dr Sondern Might we have that motion repeated to us?

The Assistant Secretary read the substitute motion

That the President be empowered to appoint a special committee to consider this particular problem—that is, the cost of medical care—and report to the Council of the Society of the State of New York for the purpose of giving that information to the public

Dr Sondern That would scarcely be a proper resolution for the delegates to carry

Dr Aranow May I suggest that the original resolution be read

Dr Rooney, of Albany I move that this House instruct its delegates to the American Medical Association to take such steps and prepare such resolutions for presentation to that house as will forward promptly the investigation of the question of the cost of medical care of the sick and the proportion borne by these various factors entering into this cost

Dr Aranow I withdraw my motion

Dr Phillips I do also

Dr Rooney's motion was seconded, put to a vote and carried.

50 LIMITING DOSAGE OF ALCOHOL (SEC. 48)

Dr Kosmak Your Committee on New Business C has considered the resolution introduced by Dr Chalmers of Queens, relative to the restriction in the therapeutic use of spirituous liquors

Your Committee hereby recommends the adoption of said resolutions

I move the adoption of the report

Motion seconded, put to a vote and carried

51 RETIRED MEMBERS

The Secretary I have a number of candidates for retired membership The By-Laws read that retired members of this Society shall be active members of component county societies seventy years of age or over who have applied for such retired membership The following have been recommended by their respective county societies Christopher S Best, Middleburg, Henry C. Coe, New York, Walter C Crombie, Mechanicville, J Baxter Emerson, New York, Wolff Freudenthal, New York, Menzo W Herriman, Long Island City, S Adolphus Knopf, New York, Charles H Ludlum, Hempstead, W Golden Mortimer, New York, George J Moser, New York, Isaac H Reiley New York, G W Rossman, Ancram, Peter Scott, Brooklyn, Peter Stockschlaeder, Rochester, George Schoeps, New York, Charles A. Wall, Buffalo, Ludwig Weiss, New York, Joseph C. Willson Canton, Thomas Wilson, Hudson, Lettis H. Woodruff, Rochester

I move that they be placed on the retired list. Motion seconded, put to a vote and carried

Motion to adjourn being made and seconded, the motion was put to a vote and carried, and the meeting adjourned to Tuesday, June 4th, at 9 30 A. M

The first That the House of Delegates of the Medical Society of the State of New York extend to Commissioner Frances Perkins our thanks and appreciation for the efficient and careful consideration of the medical problems before the Advisory Council and that we hereby offer to her all facilities at our disposal to further aid in the solution of such problems. We recommend unanimous and hearty approval.

The second proposed resolution To establish a workmen's Compensation Reference Bureau and that this bureau maintain a trained executive on full time salary is approved by the Reference Committee after the elimination of the words full time.

Third resolution To determine the status of the Life Extension Institute and define the term practicing medicine by judicial decision has the approval of the Reference Committee.

In regard to the fourth and final resolution recommended by the Committee on Medical Economics, to established minimum salary for employed physicians, stated in these words "that all organization employing doctors shall pay a minimum fee of $5 00 per hour to such doctors" Following is the reaction of the Reference Committee. We deplore the exploitation of the individual doctor by organizations utilizing his services, and further agree that there is great disparity in the salaries paid to doctors by public health, welfare, charity organizations and similar societies The Committee feels that it would be unwise at this time to attempt to fix a minimum fee of $5 00 per hour in view of the many varying factors and circumstances which prevail throughout the State We disapprove of this resolution and recommend that the State Society urge its members to expect and request for such professional service, a fee commensurate with the character and scope of the work undertaken, as modified by individual factors—

I move the adoption of the report.

The first resolution was duly seconded, put to a vote and carried

The Secretary The second resolution carries with it an expenditure of funds and has therefore to be referred to the Council.

The Speaker Dr Flaherty, if you will eliminate that part of your report that deals with the appropriation of money and refer that recommendation to the Council I will entertain the motion.

Dr Flaherty I accept the amendment.

The motion on the second resolution, as amended, was put to a vote and carried

Dr Flaherty then read the third resolution, which was duly seconded

Dr Sondern, of New York It appears that this requires a legal decision, the employment of legal talent to obtain it, and probably court procedure, and as that means the expenditure of money, I would amend the motion to refer this to the Council for action

Dr Flaherty I accept that amendment.

Dr Thomson, of Kings Hasn't it been determined by the Attorney General that no one may proceed in a similar way as the Life Extension Institute, because the Life Extension Institute is practicing medicine? In other words, if you were to make application to establish in Brooklyn a similar institution you would be turned down on your incorporation papers because you were practicing medicine illegally, or as a corporation

Dr Heyd, of New York The status of the Life Extension Institute was under a long period of investigation by the Medical Society of the County of New York The Attorney General of the State it is my recollection decided the Life Extension Institute was not practicing medicine under the terms of the law The County Medical Society of New York rested with that decision If the State Society, as Dr Sondern has indicated, wishes to make a test by swearing out an indictment against the Life Extension Institute it is going to cost money, there is no question about it. It is not a motion which should be idly or lightly accepted, and it is my view that a legal battle, the end of which is not visible, will be involved.

The motion as amended was put to a vote and carried.

Dr Flaherty read the concluding paragraph of the report and moved its adoption. Whereupon, the motion being seconded, was put to a vote and carried.

Dr Flaherty moved the adoption of the report as a whole. The motion was seconded, put to a vote and carried

42 REPORT OF TREASURER AND TRUSTEES (Journal May 1, pages 510, 515)

Dr Cady, of Cayuga The Reference Committee on Reports of the Treasurer and Trustees, approves and recommends the adoption of the report of the Treasurer The Committee approves of that portion of the Trustees' report in reference to the accumulation of a trust or investment fund of $150,000, half of which is already in hand and with the following suggestion that the fund be created solely from the accrued yearly surplus and without incurring any further financial obligation on the part of the members of the Medical Society of the State of New York.

The committee further recommends the adoption of the allocations A B C and D, as suggested by the Board of Trustees

I move the adoption of the report

Motion seconded, put to a vote and carried.

43 COMMITTEE ON MEDICAL RESEARCH (Journal May 1, page 521)

Dr Farmer The Report of the Reference Committee on the Report of the Committee on Medical Research

The reference committee on the report of the Committee on Medical Research has carefully reviewed the Committee's report.

The report indicates clearly that the Committee has been alert to protect the safeguards for scientific medical research It is also noteworthy that the Committee has clearly differentiated between true scientific research and questionable experimentation by unqualified persons

Our recommendations are as follows

That the action of the Committee during the past year be approved

That the policy governing such actions be endorsed.

That the Medical Society of the State of New York thank the Chairman and members of the Committee on Medical Research for the services which they have rendered during the past year

I move the adoption of the report Motion seconded and carried

44 CARD INDEXES FOR COUNTY SOCIETIES (SEC. 34)

Dr Douglas, of New York The Committee on New Business A, is ready to report on the resolution of Dr Hambrook of Rensselaer as follows

The Committee on New Business A, are in sympathy with the purpose of the resolution introduced by Dr Hambrook of Rensselaer, to provide cards for indexing members, but as this resolution calls for the expending of money it must under the Constitution be referred to the Council and the committee so recommends

I move the report be accepted and its recommendation adopted

Motion seconded, put to a vote and carried

45 A PHYSICIAN ON THE STATE INDUSTRIAL COMMISSION (SEC. 27)

Dr Kosmak of New York Your Committee on New Business C, reporting on the resolution introduced by the Bronx Delegation urging the passage of a bill amending the Compensation Act so as to provide for the appointment of a physician on the State Industrial Commission recommends its approval

I move the adoption of the report. Motion seconded and put to a vote and carried.

Rooney are practically my sentiments, but I think while the injured person has his primary right of choosing his own physician it might be well to give the employer consultation rights with the employee.

Dr Kaliski, of New York I want to voice the sentiment of New York County, which has gone repeatedly on record for the free choice of physicians That is embodied practically in the resolution of Dr Rooney and we would like to see the House adopt that resolution.

Dr Bowen, of Livingston We lose sight of the fact the employer is anxious to get the employee back on the job as soon as possible. In many cases we have to deal with an employee ignorant, excited, anxious for compensation, who wants to run to everybody he hears of, who is coached by charlatans, and we are asking the employer to pay for all of that foolishness It seems to me it is to the interest of the employer or the insurance carrier to have a competent man to look after these employees

Dr Cottis, of Chautauqua I think the last remark should be considered, and I think we should have a separate law for Greater New York than for the rest of the State. I know that is impracticable, but in the smaller industrial regions the local life insurance companies and local manufacturers are as anxious as we are that employees have good care.

Dr Rooney, of Albany There is nothing in this law or resolution that will prevent the employer or insurance company having any physician they desire see the patient and oversee the treatment, they are given that right in the laws that exist, they have a right to have consultation and make such choice of consultants as they choose. Gentlemen, let us try to keep our eye on one point. We only stand for one thing—the best kind of practice that can be given to the injured employee.

The motion was then put to a vote and carried

54 COMMITTEE ON ARRANGEMENTS THANKED

The Secretary I wish to move a vote of thanks and appreciation of the work done by the Committee on Arrangements, thanking them also for the generous hospitality of the County Society that they represent.

Motion seconded and carried

55 SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

The Secretary I have a request that a section on Gastro-enterology and Proctology be formed. I move it be referred to the Council.

Motion seconded, put to a vote and carried.

56. TELEGRAM TO DR. STOVER

Dr Wightman Mr Speaker, it has just been called to my attention that Dr Charles Stover, of Amsterdam, an ex-president of this Society, is ill at home, unable to be here as a delegate. I would like to move you that the sympathy of this body be tended to him with our best wishes

Motion seconded, put to a vote and carried.

Dr Farmer A short time ago a motion was made to send a telegram to Dr Stover and I was very glad to know that action had taken place. I think this House of Delegates at this time should also send a telegram to our oldest living resident, Dr Albert Vander Veer of Albany, extending to him our heartiest greetings and best wishes I so move.

The motion was seconded and carried.

57 ADJOURNMENT

On motion of Dr Rooney, duly seconded, the House adjourned sine die.

JOHN A CARD, *Speaker.*
DANIEL S DOUGHERTY, *Secretary*

ADJOURNED SESSION OF THE HOUSE OF DELEGATES, TUESDAY, JUNE 4TH, 1929

52 ROLL CALL

The meeting was called to order by the Speaker at 9 30 A M

The Speaker The Secretary will please call the roll.

The Secretary called the roll and the following delegates responded

William P Howard, Thomas W Jenkins, Brayton E. Kinne, Lyman C Lewis, J Lewis Amster, Harry Aranow, Cornelius J Egan, Louis A. Friedman, Vincent S Hayward, Jacob A Keller, Edward C Podvin, Edmund E Specht, Howard W Davis, Charles D Squires, Seth N Thomas, George W Cottis, Reeve B Howland, Leo F Schiff, Henry J Noerling, Charles D Ver Nooy, C Knight Deyo, William A Krieger, Aaron Sobel, John D Bonnar, J Henry Dowd, Mary J Kazmierczak, John Breen, Charles C Trembley, Sylvester C. Clemans, William D Johnson, Norman S Cooper, John L. Crofts, Norman L. Hawkins, Jefferson Browder, Elias H Bartley, Eugene Marzullo, Adolph Bonner, Thomas N Brennan, Peter J Dulligan, Cameron Duncan, Frederic E. Elliott, Edwin H Fiske, Harold C Denman, Edwin A. Griffin, Augustus Harris, Nunzio Rini, John E. Jennings, Alec N Thomson, Alexander L. Louria, Charles T Graham-Rogers, Joseph W Malone, John J Masterson, Joseph Raphael, Charles E Scofield, James Steele, Luther F Warren, Harvey W Humphrey, Frederick J Bowen, Charles R. Barber, Clarence V Costello, Joseph P Henry, Floyd S Winslow, Horace M Hicks, George B Granger, Albert M Bell, Emily D Barringer, Edward M Cohe, Jr, Walter H Conley, Walter T Dannreuther, Edward J Davin, John Douglas, Ten Eyck Elmendorf, B Wallace Hamilton, Ward B Hoag, Albert S Hyman, David J Kaliski, Samuel J Kopetzky, George W Kosmak, Otto H Leber, J Milton Mabbott, Henry S Patterson, William M Patterson, Alfred C. Prentice, Nathan Ratnoff, DeWitt Stetten, Henry K. Taylor, Terry M Townsend, Louis Tulipan, William A. Peart, Frederick J Schnell, George M Fisher, Joseph L. Golly, Andrew Sloan, Thomas P Farmer, Frederick H Flaherty, Albert G Swift, Charles W Selover, Joseph B Hulett, Charles E Padelford, Harvey S Albertson, Carl Boettiger, Thomas C Chalmers, Henry C. Courten, William J Lavelle, Francis G Riley, Ernest E Smith, Augustus J Hambrook, John H Reid, George A. Leitner, W Grant Cooper, Stanley W Sayer, George S Towne, Dudley R. Kathan, Frederick C. Reed, Henry R Bentley, Robert M Elliott, Leon M Kysor, Herbert B Smith, Frank S Child, Luther C. Payne, George M Cady, Luzerne Coville, Carl F Meekins, Morris Maslon, Walter A. Leonard, Lucius H Smith, Harrison Betts, Merwin E Marsland, Romeo Roberto, George B Stanwix, William N Miller, George E Welker, George Manley

The following Officers, Trustees and Chairmen of Standing Committees were present

Harry R Trick, James N Vander Veer, Thomas H Farrell, Daniel S Dougherty, Peter Irving, Charles G Heyd, John A. Card, Walter D Ludlum, Thomas P Farmer, Arthur J Bedell, James E. Sadlier, Frederic E Sondern, Hyzer W Jones, Edward R. Cunniffe, Guy H Turrell, Edgar A. Vander Veer, Paige E Thornhill, LaRue Colegrove, Austin G Morris, Nathan B Van Etten, Grant C Madill, William H Ross, James F Rooney, Arthur W Booth

The following Ex-Presidents were present Wendell C Phillips, Grant C Madill, J Richard Kevin, James F Rooney, Arthur W Booth, Orrin Sage Wightman, Nathan B Van Etten, George M. Fisher

52 ELECTION OF OFFICERS

The Speaker announced that the meeting would proceed to the election of officers and the following tellers were announced by the Secretary

Edward M Cohe, Jr, New York, Chairman, Vincent S Hayward, Bronx, Reeve B Howland, Chemung, William A Krieger, Dutchess, Thomas M Brennan, Kings, Frederick H Flaherty, Onondaga, George A. Laitner, Rockland, William P Howard, Albany, Aaron Sobel, Dutchess-Putnam, DeWitt Stetten, New York, Andrew Sloan, Oneida, Thomas Chalmers, Queens

The Secretary announced that Dr William H. Ross had resigned from the Board of Trustees, and moved that his resignation be accepted Motion was seconded, put to a vote and carried

The following officers were nominated and elected

President Elect, Dr William H. Ross, Brentwood, First Vice-President, Dr Floyd S Winslow, Rochester, Second Vice-President, Dr Lyman G Barton, Plattsburg, Secretary, Daniel S Dougherty, New York, Assistant Secretary, Peter Irving, New York City, Treasurer, Charles Gordon Heyd, New York City, Assistant Treasurer, James Pedersen, New York City Speaker, John A Card, Poughkeepsie, Vice-Speaker, George W Cottis, Jamestown, Chairman, Committee on Scientific Work, Arthur J Bedell, Albany, Chairman, Committee on Legislation, Harry Aranow, Bronx, Chairman, Committee on Medical Economics, Benjamin J Slater, Rochester, Chairman, Committee on Public Health and Medical Education, Thomas P Farmer, Syracuse, Chairman, Committee on Public Relations James E. Sadlier, Poughkeepsie, Chairman, Committee on Medical Research, Frederic E. Sondern, New York City, Trustees, Nathan B Van Etten, for five years, Harry R. Trick for two years, to fill unexpired term of William H Ross, resigned

The following were elected Delegates to the American Medical Association for 1930-1931

Daniel S Dougherty, Nathan B Van Etten, George A. Leitner, James N Vander Veer, Orrin S Wightman, J Richard Kevin, Samuel J Kopetzky

The following was elected delegate to the American Medical Association for 1929-1930

Harry R. Trick, Buffalo

The following were elected Alternates to the American Medical Association for 1930-1931

John E. Jennings, Edward A. Griffin, Charles H. Goodrich, Edward J Cunniffe, W Warren Britt, William D Johnson, Edwin H Fiske.

The following was elected Alternate to the American Medical Association for 1929-1930

Thomas W Jenkins, Albany

53 CHOICE OF PHYSICIAN BY INJURED WORKMAN (SECS 26 AND 46)

The Speaker The Committee on New Business C has a report.

The Secretary It was deferred until such time as counsel, Mr Stryker, could be here and take the floor

The Speaker Mr Stryker will please come forward. The House will listen to Mr Stryker, our counsel.

Mr Stryker addressed the House.

The Secretary Mr Speaker, the House should consider first the adoption of the report of the committee and then offer it for discussion.

Dr Rooney, of Albany I withdraw my previous motion I move you, sir that this house refer this matter to the Legislative Committee of this Society

The Secretary We must accept the report first.

Dr Rooney Then I withdraw my motion and I move you that we accept the report of this committee

Motion seconded, put to a vote and carried

Dr Rooney I move that the matter embodied in this report of the Reference Committee C be left to the Legislative Committee of this Society with the recommendation of the House that in so far as they believe it wise and judicious that an amendment will be proposed to the Workmen's Compensation Act providing for the free choice of a physician by the employees, and that that is the sentiment of this House.

The motion was duly seconded

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Montefiore Hospital, on June 18, 1929, was called to order at 9 15 P M, the President, Dr Aranow, in the Chair

Election of candidates being in order, it was moved and carried that the Secretary be instructed to cast one ballot for the following candidates for membership Louis Abelson, John G Codik, John A Colucci, William Director, Samuel J Ehrlich, Abraham Gillman, Louis Heyward Harris, James F Hart, Jacob Jacobson, Isaac Jampol, Abraham J Julius, Fannie Isabelle Kapp, I John LaRosa, Edward N Lefcourt, Harry S Nemens, Jacob L Olenik, Samuel J Schneierson, Jacob M Schwarsbram, Edith Tschner and Geza Weitzner

Dr Aranow reported on the recent Annual Meeting of the Medical Society of the State of New York and the satisfactory work done by the Delegates representing our Society

The Scientific Program proceeded as follows

CLINICAL MEETING

1 Types of cardiac failure—S P Schwartz
2 Treatment of Advanced Cardiac Failure—L Tarr
3 Pernicious Anemia Neurological Manifestations—M Keschner
4 Medical Aspects of Surgery in Pulmonary Tuberculosis—J J Wiener, M Fishberg
5 Cases from the Surgical Service—I Cohen, J Gottesman, J M Ziegler
6 X-ray Demonstration of Metastases—A J Bendick.

It was moved and carried that a vote of thanks be extended to Montefiore Hospital and the gentlemen who presented the Cases

Respectfully submitted,
I J LANDSMAN, M D, *Secretary*

NOISE IN NEW YORK CITY

New York City has an anti-noise society whose objects are described in an editorial in the New York *Times* of June 12

"Pity the Board of Aldermen if the New York Anti-Noise Society succeeds in carrying out its plan to go before the city fathers and, for the space of two minutes, subject them to a select combination of New York's commonest noises!

"What to do about it not even the Anti-Noise Society seems to know Doubtless within a generation or more the public will have either gone mad or developed protective deafness, or have insisted that scientists devise ways of muffling the noises that are the by-products of machines of various sorts, from brakes and exhausts to squeaks and rattles Present city dwellers seek to develop voices able to be heard above the roar

"Political philosophers comfort us with the observation that it is not so long since 'offenses to the nose' were as common in our cities as they still are in the remote regions of China, where there is no drainage or system of refuse disposal and the streets are filled with decaying litter Yet these things, in the name of public health, are now under control There are indications that 'offenses to the eye' in the form, notably, of unsightly rural billboards, are coming within the police power It may be that the public will in time educate lawmakers to suppress offenses to the ear as readily as offenses to the nose and the eye—including much more than unmuffled motors, excessively loud bells and gongs and other sounds which are at present covered by laws and codes"

HEALTH CONTEST FOR CITIES

What New York City has done, other cities can do,—probably better The National Chamber of Commerce is starting a contest among cities to see which one can do the best work in public health The New York *Herald-Tribune* of June 20 describes the proposed contest as follows

"The inauguration of a national health contest, designed to place on a comparable and competitive basis community effort throughout the country in checking economic losses due to disease and premature deaths, was announced today by the Chamber of Commerce of the United States It will be known as the National Inter-Chamber Health Conservation Contest and will be similar to the National Fire Waste Contest in which more than 650 towns and cities are now enrolled

"The period covered by the contest will be from January 1 to December 31, 1929 Awards will be based principally upon the organization and equipment of local health departments, financial support of health activities, both official and voluntary, and facilities for health information and education, water supply, milk supply, sewage disposal and health laws and ordinances

"To all cities entering the contest there will be made available, free of charge, expert assistance from the American Public Health Association and other cooperating organizations, within the limits of their resources, in analyzing conditions and initiating activities for improvement of health conditions"

GORILLA ANATOMY

A joint expedition of Columbia University and The American Museum of Natural History under Dr Henry C Raven, will go to Africa to secure specimens of gorillas for anatomical study Concerning the objects to be attained the New York Herald Tribune of May 24 says editorially

It is a misfortune of biology that the wrong animals happened to be domesticated Had man's first companions chanced to be the chimpanzee and the gorilla, instead of the dog, the horse and the pig, scientists would now know far more than they do about the mental and physical make-up of these apes and their relatives—creatures indubitably closer to the make-up of man than are any other forms of life. Domesticated apes might have been useful, too, in industry and household economy, for an experience of a hundred centuries or so in human companionship might easily have bred docile and intelligent gorillas competent for many tasks now carried out by men or by machines The chance to understand a gorilla's mind even as well as we glimpse the minds of horses or dogs is probably gone forever But the creature's body, with all its important implications for the theory of evolution, science ought to know far better after the expedition of our two New York institutions has returned and given its report"

THE DAILY PRESS

HEALTH OF NEW YORK CITY

The health forces of New York City are discussed editorially in the New York *Herald-Tribune* of June 4 in a way which would do credit to a medical Journal It says

"It's not a bad place to live in, this New York of ours They denounce it on the hustings as a center of moral and physical disease, but the figures do not bear them out Indeed, the baby born in New York, partly because he meets all the germs young, has a better chance of coming through life triumphantly than many a country child whose milk is not inspected, who grows up far from doctors and medical inspections and never learns to meet temptations and disease. The Health Survey of the city, a sort of hygienic regional plan just carried out by the Welfare Council, gives this smoky, crowded, sweating city a rating of 709 out of a mysterious 1,000 possible health scores—which is certainly better than it would rate on a transit scorecard

"The growth of public health work is one of the impressive phenomena of our period, and this survey naturally discloses weak spots and lopsided developments Manhattan, for instance, with less than a third of the city's total population, has more health services than the four other boroughs combined

"We still lay the old emphasis on cure rather than prevention of disease—we spend $150,000,000 annually for the treatment and only $8,500,000 on various forms of preventive work But New York hospitals are pioneers in the preventive clinical and education work which, in some remote future, may make hospitals almost unnecessary And while the municipal Health Department is one of which New York may well be proud, we might well be even prouder In 1927 New York spent an average of 91 cents upon the health of each citizen of the city, but Chicago spent $1 29 and Boston $1 53

"Many of the findings of the survey are technical, they suggest lines of development and coordination among the various existing health agencies In particular, they suggest that the function of the municipal Department of Health is likely to become increasingly to guide, coordinate and assist the work of semi-private health institutions and bodies rather than to administer health services directly This is most obvious in the expanding field of preventive work."

MOVIES IN TEACHING HYGIENE

The place of movies in teaching is being debated pro and con The truth is that moving pictures cannot take the place of hard study, but they can help to visualize conditions which cannot be seen Peristatsis, for example, is an unknown action even to physicians, unless they have seen a living stomach in action, or, better still, an animated series of *x*-ray pictures which repeat the action over and over in a vivid way

The New York *Times* of June 21 has the following item concerning moving pictures in the public schools

"Motion pictures of parts of the human body in action were publicly demonstrated by Professor Clair E Turner of the Massachusetts Institute of Technology at an evening session of the health educational conference of the American Child Health Association

"These reels represent part of a million-dollar program initiated by the camera industry in an effort to develop a subdivision of their industry which would manufacture such material for everyday use in the classrooms of the public schools, according to Professor Turner, who is in charge of the work

"During the day summaries of the recommendations and conclusions arrived at by their previous special sessions were drawn up by the various sections The elementary school section presented its preliminary report at the general session tonight

"Copies of the films shown by Professor Turner will be ready for distribution to the school systems throughout the nation at the beginning of the coming school year They will be sold for $35 each.

'The comment of the educators attending the conference was that such moving pictures would greatly affect the future of school children Instead of finding school work a dry task, the pupils would be able to see their various tasks as delightful experiences, they pointed out

"The action of tiny microscopic digestive glands in the stomach and intestines was portrayed by one of the pictures Another showed the processes of swallowing and the churning of the stomach In the making of these pictures the *x*-ray was used in order to show the movements Circulation of the blood in the embryo of a chicken was also pictured"

Prevent Summer Diarrhea!

FREE from pathogenic bacteria, the use of Dryco avoids milk-borne diarrhea, enteritis and other similar disorders. This is the season when such infections become increasingly prevalent. Prescribing Dryco now, means the elimination of many summer feeding troubles

In cases of disturbed infantile metabolism, when various formulæ fail to produce the desired result and nothing else agrees try Dryco It is well borne when other forms of milk are not tolerated and has proved its merit in thousands of difficult feeding cases over a period of many years

Send for suggested feeding tables, Dryco samples and clinical data

OUR NEIGHBORS

HOW MICHIGAN DOCTORS WORK IN MEDICAL LEGISLATION

The physicians of Michigan have set an example to the doctors of other states in the way they worked legislative matters Read the following account from the June issue of the Michigan State Medical Society

"SESSION ACTIVITY"

"Our two bills were introduced by Senator Engel and referred to the Committee on Public Health of the senate, of which Dr James T Upjohn of Kalamazoo was chairman

"At about the same time there was introduced in the house a chiropractic bill Later, in the senate, the osteopathic bill was introduced

"Now followed a seemingly unending, ever varying, hectoring and trying train of conferences, interviews and discussions that continued through to the last day of the session They served to also clearly reveal the modern style of political methods They were concerned with legislators, lawyers, chiropractors, osteopaths, druggists, Christian Scientists, beauty specialists, spiritualists, barbers, publishers of papers, optometrists, chiropodists, and fanatics All of them being incorporated in our bills or who felt we were tying a noose about their necks Even some of our own members created added problems and difficulties It was a herculean task to deal with these varied groups with their particular quests That task was discharged at no little cost of temper and worry

"One public hearing was had on the osteopath's bill This hearing was attended by some 200 osteopaths and their attorney, who was their spokesman Our society was represented by Dr Guy L Kiefer, Dr R E Loucks, Dr A H Whittaker, Dr G C Penberthy and the Secretary

"Eventually the four bills were reported out to the senate and all of them passed the senate The chiropractic bill was accepted and no oppositions were made to it Our opposition to the osteopathic bill was unavailing, largely due to a speech made on the floor of the senate by its introducer This distorted and unreliable speech was later answered by an open letter to all the members of the legislature and our position set forth

"Under the rules, the bills went to the house and were referred to the Committee on Public Health of the house The chiropractic bill went to the Governor and had ten days in which to be signed or vetoed A gentlemen's agreement was entered into with the chairman of the House Public Health Committee whereby he was to report our bills out in five days so that they and chiropractic bills could be signed on the same day The five days passed and eight days passed. But two days remained within which our bills had to be reported out and passed or failing, the Governor had to veto the chiropractic bill to prevent it from becoming law

"The Governor was a patient in a Grand Rapids hospital He was interviewed He gave us a message at 4 P M A hurried trip, through a terrific rain storm, was made to Lansing Interviews were had with the committee chairman who then finally showed his hand and informed us he would not report out our bills The Detroit men were called to Lansing and the conference continued till after midnight Early the next morning the return trip was made to Grand Rapids The Governor was again seen and later in the day his secretary came to Grand Rapids with the formal veto which the Governor signed at five o'clock—twelve hours remaining ere the chiropractic bill would have become law were it not vetoed

"An interval now intervened in which, by request, several members were called to Lansing for a conference with Senator Woodruff and Governor Green The osteopaths' representative thought a compromise might be accepted Our position was definitely stated and by its terms a compromise was not made We were informed a 'fight would be on' Requests were then sent to all county societies to increase their protests to members of the house Again there was evidenced some very good activity by some parts of the state while others remained dormant.

"A week intervened with no outward evidence of any move by the Legislative Public Health Committee Then on May 1st, seven days before adjournment, word was passed out that the chiropractic bill which had been vetoed would be tacked on as an amendment to our professional qualification bill and so reported out with the osteopathic bill On May 2nd the Public Health Committee of the house reported out the osteopathic bill, our bill amending the Medical Practice Act and the Professional Qualifications Act which had tacked onto it as an amendment the vetoed chiropractic bill Your officers and commission felt that they had made sufficient contact with the legislature and therefore refrained from further activity It was concluded that the best course now would be to permit the legislature to record their vote If the osteopathic bill passed, our last recourse would be Governor Green

ALIS PRODUCTS, Inc.
226 Lafayette St., New York City

(*Continued from page* 840)

"On May 6th the house passed the osteopath bill The Professional Qualification Act was reported out with the previously veteod chiropractic bill attached to it as an amendment. Under the rules both bills were returned to the senate where the osteopath bill was again passed and on a parliamentary point the qualification act with the chiropractic amendment was ruled out of order The legislature adjourned on May 8th with the result that only the osteopath bill had weathered the session and was before the Governor for signature

"There now arose the final somewhat hectic incident After the adjournment, the Governor was flooded with some 2,000 telegrams urging him to sign the osteopath bill—more telegrams than he received on the 'Death Penalty Bill.' Then about two o'clock, on the afternoon of Saturday, May 11th, the information came through from a reliable source, that the attorneys for the osteopaths had filed with the Governor a lengthy brief substantiating in a most impressive way the osteopathic claims To the uninformed these claims had face appearance of being conclusive facts, but upon analysis were grossly unsubstantiable It was necessary to supply the Governor with refuting facts from reliable authorities Long distance was employed far into the night. On Sunday, May 12th, our results were transmitted to President Hirschman, Dr Kiefer and Dr Whittaker in Detroit and it was concluded that because of the nature of our returns and an intimation that had been received that a statement from Dr Ray Lyman Wilbur, secretary of interior and also president of the American Association of Medical Colleges, was of uttermost importance The pre-emptive order was to come to Detroit A plane was secured, in an hour and fifteen minutes Detroit was reached With Doctors Hirschman, Kiefer and Whittaker the entire situation was reviewed An endeavor was made to summarize the situation in a telegram but it was impossible to do so because of the many related points that were necessary to clearly visualize the situation for Dr Wilbur The conclusion was that the Secretary should board a train and go to Washington because our representation had to be in the Governor's hands by Tuesday, the 14th This conclusion was reached at four o'clock Reservation was secured on a six o'clock train, a pair of pajamas was purchased and Washington was reached at noon on Monday Dr Wilbur was interviewed at one o'clock and by three o'clock his signed statement was in our hands A taxi enabled the catching of the 3 30 train that reached Detroit at 9 a m Tuesday and Lansing was reached in the afternoon The obtained statements and exhibits were placed before Governor Green at 4 p m

"Governor Green vetoed the osteopathic bill"

FELLOWS' SYRUP

of the Hypophosphites

A concentrated mineral pabulum, possessing unrivalled therapeutic properties in all Wasting Diseases, which have been termed "Demineralizations" by modern clinicians.

Supplies the organism with those indispensable mineral elements:

POSTGRADUATE WORK IN NEBRASKA

Dr J Stanley Welch, writing editorially in the May issue of the *Nebraska State Medical Journal,* says

"Postgraduate work? Yes! But how?

"At Vienna or some foreign medical mecca, perhaps as an interrupted vacation period

"At your alma mater, perhaps remotely located and divorced from you by years

"At the nearest, but to you strange, university medical college

"At your county or district medical meeting as an organized week-end teaching assembly

"At the hospital in your area best organized for teaching

"OR, not at all, like myself

"Postgraduate work I certainly need, but how shall I get it? Today we are accused of graduating Super-Six, -Eight or -Twelve cylinder doctors and putting them on the road with no service stations to maintain them Where will you, doctor, general practitioner, get your fouled medical spark plug cleaned today?

"To organize a teaching team and function it for a two or three day period at stated places costs time and money, and some such experiments have been very disappointing Perhaps they were not in your area Perhaps you did not know about them That was not your fault That was the fault of the organization What we now ask is, "Do you want any of these types of postgraduate work?"

"Three states near us have had courses of nine week's duration, one day a week, in organized districts Thirty doctors were previously registered and paid a cost fee Three classes succeeded especially well where good teachers were procurable Indeed, these three states that success seems dependent on this factor Good teachers are not to be found here, there and everywhere at any time It may be possible to procure through some central body such as the American Medical Association, the Carnegie or Rockefeller Institute, the continuous services of such a teaching staff, providing several states would cooperate Would you subscribe to such an endeavor to bring postgraduate study to your district?"

BUREAU OF INDUSTRIAL HYGIENE

The Michigan State Department of Health has a bureau whose objects are set forth in the June issue of the *Journal of the Michigan State Medical Society* as follows

"A Bureau of Industrial Hygiene has recently been created in the Michigan Department of Health, a division of public health service looking to the interest of industrial and mercantile establishments in their efforts to safeguard the health of their employees

(Continued on page 846—Ad

WHEN A DIABETIC SAYS:

"What can I eat that tastes good?"

One of the problems in diabetes is to keep the patient diet-happy! And Knox Sparkling Gelatine can be of real service.

As you will note in the recipe below, Knox Gelatine combines perfectly with the foods prescribed for the diabetic diet. It makes dishes that are appetizing and *different* to the eye and the taste. It supplies the diet variety that satisfies the patient's appetite and it supplies the food-bulk that the patient's hunger craves.

People suffering from diabetes really enjoy gelatine dishes—and they *can* enjoy them if they have our diabetic recipes prepared by one of the country's recognized dietitians. Remember, Knox Gelatine is free from *sugar*.

KNOX *is the real* GELATINE

Contains No Sugar

WINTER SALAD *(Six Servings)*

	Grams	Prot.	Fat	Carb	Cal.
2 teaspoons Knox Sparkling Gelatine	4.5	4	—	—	—
¼ cup cold water	—	—	—	—	—
½ cup hot water	—	—	—	—	—
½ teaspoon salt	—	—	—	—	—
¼ cup vinegar	—	—	—	—	—
1½ cups grated cheese	150	43	54	—	—
½ cup chopped stuffed olives	70	1	19	8	—
½ cup chopped celery	60	1	—	2	—
¼ cup chopped green pepper	25	—	—	1	—
½ cup cream, whipped	75	2	30	2	—
Total	381	103	13	13	1183
One serving	8.5	17	2	2	197

Soak gelatine in cold water Bring water and salt to boil and dissolve gelatine in it. Add vinegar and set aside to chill. When nearly set, beat until frothy fold in cheese, olives, celery pepper and whipped cream. Turn into molds and chill until firm. Unmold on lettuce leaf and serve.

SPINACH SALAD *(Six Servings)*

	Grams	Prot.	Fat	Carb.	Cal
1½ tablespoons Knox Sparkling Gelatine	10	9	—	—	—
¼ cup cold water	—	—	—	—	—
1¼ cups boiling water	—	—	—	—	—
2 tablespoons lemon juice	20	—	—	2	—
½ teaspoon salt	—	—	—	—	—
1½ cups cooked spinach chopped	300	6	—	7	—
2 hard cooked eggs	100	13	10 5	—	—
Total	28	10.5	9	242.5	
One serving	5	2	1.5	40	

Soak gelatine in cold water and dissolve in boiling water Add lemon juice salt, strain and chill. When nearly set, stir in chopped spinach mold and chill until firm. Serve on lettuce hearts or tender chicory leaves and garnish with hard cooked egg cut lengthwise in sixths and sprinkled with paprika Serve with mayonnaise.

If you agree that recipes like the ones on this page will be helpful in your diabetic practice, write for our complete Diabetic Recipe Book—it contains dozens of valuable recommendations. We shall be glad to mail you as many copies as you desire. Knox Gelatine Laboratories, 432 Knox Ave., Johnstown, N Y

"The general purpose of this bureau is to keep in practical touch with the health problems affecting industrial workers, to become familiar with the changes constantly taking place in the rapidly growing and highly specialized field of industrial hygiene, to be able, thereby, to give counsel and aid, as occasion may demand To this end the main functions of the bureau will be

"1 To study the general progress of health service in industries in relation to the various influences that affect the physical and mental well-being of men and women in their employ

"2 To note the types and extent of health service best adapted to Michigan industries, dependent upon their size and the nature of work conducted

"3 To aid in devising and establishing generally accepted standards for practical application of hygiene in industries

"4 To secure data on important items such as occupational diseases and industrial hazards

"5 To establish consulting and advisory relations with health departments of industries, to serve as an exchange medium for procedures proved to be most effective in health promotion and care

"6 To supervise the collection, preparation, and distribution of pamphlets, bulletins, and other material for education in industrial hygiene

"7 To aid in establishing cooperative relations between health departments of industries and local health departments, medical societies, and district nursing, welfare and educational units

"The first step toward the establishing of this bureau was to conduct a survey of industrial and mercantile establishments to learn the nature and extent of health service now being promoted by them, to discuss with plant executives some of the main objectives of their health work, to get their reactions and recommendations as to the value of certain measures, also their anticipated improvements, and to offer any assistance possible from the Michigan Department of Health

"The survey has thus far covered about 100 establishments with employes numbering from 150 to 30,000 No particular preference was shown as to industries visited, the aim being to visit those in which could be observed both the very limited and the most inclusive scope of measures employed in the care of injured and ill employees

"The items noted in the survey are Staff of physicians and nurses, equipment, physical examinations, dispensary or health department service, relations with 'family' physicians, safety measures, welfare programs, benefits derived from the health service in general, and recommended variations and improvements

"The data gathered in this general survey is enlightening as to the rapid growth and possibilities of industrial health work. It is also reassuring as to the valuable contribution well organized health work in industries can make to the field of public health A resume of some of the significant points brought out by the survey will be included in these columns next month"

WHY PEOPLE SUPPORT CULTS

The *Journal of the Michigan State Medical Society* for June contains the following letter from a Michigan banker who also is a member of the State Legislature

"This letter is in reply to your communication of April 16th to the members of the House of Representatives, and also in reply to the printed circular under date of April 3rd forwarded to us by Dr Warnshuis, Secretary of the Michigan State Medical Society

"In making this reply to you, I do so entirely in the spirit of constructive criticism, holding no brief for osteopaths, chiropractors, or any other school of mechanical or faith-healing, and having in mind, and extending full respects thereto, those sterling, Christian gentlemen who put personal and penurious interest behind them, and look only for the welfare of their patients I refer to those doctors who look at their profession from the consumer's angle, which, after all, is a mighty fine way any of us should view his or her daily activities

"The provisions of the osteopaths' and chiropractors' bills are bringing to the mind of each of the members of the House of Representatives the inference that all is not well in the public mind with regards to the standing of the members of the A M A, and the present difficulties that the medical fraternity are experiencing in the Michigan legislature may be considered as a reaction of the general public to the methods and practice employed by SOME of the medical doctors during recent years In other words, it is the handwriting on the wall that the medical Fraternity has spots on it, and is due for an internal housecleaning, properly conducted by its own members and officers

"Within the last eighteen months, an eminent surgeon, during a gathering of men of his kind in an eastern city (and I deplore the fact that I lost the newspaper clipping, which I have had occasion to quote many times) stated that 95% of the surgery performed in America was needless, was merely inflicting a permanent wound on the body, and in the long run was discrediting the medical profession in the eyes of the consuming public You may know of, off hand, to

(*Continued on page 849—adv xxi*)

(*Continued from page 848—adv xx*)

whom I am referring I am sorry I cannot give you his name as the clipping has been lost.

"From my own personal experience I must say that the medical services rendered to members of my family have been far from satisfactory, and had engendered in me a wholesome disgust of anyone who uses the term Specialist I will outline some of our experiences briefly

"Exhibit One—Dr X in 1915 performed an operation on my wife While the fee charged was very reasonable, the results were almost negligible Aside from this, the surgeon saw fit in his supreme ego to capitalize socially on the case I will let you draw your conclusions in your own imagination

"Exhibit Two—Dr Y in 1925 performed an operation on my wife, making a nine-inch incision for a so-called exploratory operation, and removed from her a perfectly normal appendix, as was proven after the operation by the nurse This operation resulted in very intestinal adhesions, from which the patient suffers today Of course, the bill was a trifling $300, to say nothing of the hospital expense, the pain, the fear and anguish The basic trouble for which she was operated, remains today Judge for yourself

"Exhibit Three—Dr Z in 1927 operated on my nine-year daughter for what he termed a dangerous acute case of appendicitis He removed a perfectly normal appendix, as was again proven by the nurse's testimony, sent me an invoice for $150, which was only a small part of the total cost to say nothing of the child's fear, terror and pain Aside from this ailment, which we might in days past recognize as a plain, old fashioned case of belly-ache, this child is a physically perfect specimen. Again I ask you to judge for yourself

"Our experiences are mere samples of what the public is suffering at the hands of cross-road mechanics, who style themselves as surgeons, and who proceed through their crude guess work to abstract money from people's pockets by the instrument of fear, which is the same process used by the gunman in his tactics to relieve his victims of their money Personally, I see no difference in the final outcome in either case if the surgery has been uselessly performed

"It cannot be expected that the genral public are going to forever stand defenseless against such tactics as this In my every day occupation, I am a banker, and many a wage earner comes to me soliciting a loan that his wife or some other

(*Continued on page 850—adv xxii*)

Summer Problem No. 2—
INFANTILE DIARRHEA

AGAROL is the *original* mineral oil—agar agar emulsion with phenolphthalein and has these special advantages.

Perfectly homogenized and stable pleasant taste without artificial flavoring freedom from sugar alkalies and alcohol no contraindications no oil leakage no griping or pain no nausea or gastric disturbances not habit forming.

The second summer in the life of the child is popularly believed to be the most strenuous. There probably is something to it As teething is at its height at this age period, digestive upsets may be expected Many of them will be prevented if proper elimination is made a measure of precaution

AGAROL

the original mineral oil and agar-agar emulsion with phenolphthalein, is eminently suited for children because it contains no alkali, alcohol or sugar to interfere with the digestive processes And Agarol is so palatable that children take it gladly

Shall we send you two regular size bottles with our compliments? Send for them

member of his family may have a surgical operation, and I am wondering if this surgery h been as brutal and as foolish as has been performed on my own family, as I know it tak these men anywhere from three months to a y to discharge this debt incurred for such operations Surely, the practice of "gyp" surgery the case of low paid working men is an abominable crime

"This tirade may seem a long way from discussing the osteopath bill, but I am not the only one to whom people have told that they have gone from pillar to post, from one specialist to another, submitting to costly treatments, expensive operations, only to find themselves in worse condition than when they started Some of these people have reported relief by osteopathic o chiropractic treatment. How much depends upon this latter treatment one can make, is questionable

"Now, let us sum this up into one paragraph Is the medical profession actually performing a conscientious service to the lay public that gives them a cure or a relief at a minimum of suffering and expense? That is a question for the A M A to answer, and when the A. M A. can answer this question absolutely in the affirmative, then it has a right to demand that legislative bodies the country over will protect public health by restricting business of administering to the sick to the members of the A M A

"Again, I wish to assure you that this letter is intended strictly in the sense of constructive criticism I like to see people well, and I like to see physicians prosper, but I do not like to stand by silently, just to be a shrewd politician, and see the public buncoed I feel that it is time for the A M A. to rid itself of its fossilized code of ethics, which in the long run are almost mythical, and come down to a true competitive basis that will give the public value received, the same as the manufacturer, merchant and the public utilities and other forms of human endeavor must do, in order to incur and maintain public good will"

GOVERNOR'S VETO OF OSTEOPATHIC BILL

The Governor's veto of the Osteopathic Bill is recorded on page 488 of the *Journal of the Michigan State Society* for June as follows

"To the President of the Senate

"Sir I am returning herewith, without my approval, Senate Bill No 239, File No 152

"Osteopaths have just been given the right to prescribe, administer and dispense narcotic drugs to patients, House enrolled Act No 283 which

(Continued on page 852—adv xxiv)

Patient Types . . .

The Elderly Patient

It is often a task to keep an elderly patient in active service. Constipation may be the borderline between invalidism and good health. Cathartics are particularly harmful in such a case but Petrolagar and "Habit Time" will help the senile bowel to normal function.

Petrolagar is composed of 65% (by volume) mineral oil with the indigestible emulsifying agent, agar-agar.

has received my signature But this Bill would go further and give osteopaths the right to practice surgery, and have all the other powers of doctors of medicine and surgery This law would permit those specializing in a single type of treatment to have equal privileges with those who have conformed to the requirements of a complete medical school training such as is provided at Michigan's outstanding medical school at the University

"There is a place for the practice of osteopathy I am not objecting to it as a profession Its practitioners are to be congratulated upon their constant endeavor to advance their standards and requirements I do, however, maintain that the State should not set up two separate and distinct routes through to reach the objective of receiving the sanction of the state in the complete and unlimited practice of medicine and surgery

"If, in addition to the additional privileges recently granted the members of the osteopathic profession wish to be licensed to practice medicine in all of its branches, as provided in this bill, they should meet requirements now made of those who now receive that privilege I cannot add my sanction to a bill which sets up a double standard of required qualifications

"Therefore, I veto this bill

"Respectfully,

"(Signed) Fred W Green,

MEDICAL PUBLICITY IN MINNESOTA

The doctors of Minnesota seem to have some sense of humor, or at least the editor of Minnesota Medicine has, for he publishes in the June issue the following extract from the Fairmont Daily Sentinel, April 18, 1929

"The doctor at Austin got owly at the Herald because they thought that paper in publishing the news did not sufficiently reverence the rather remarkable ethics of that profession, which pretends to be grossly insulted if they are given publicity, especially if it smacks of advertising The docs held a caucus and resoluted that the Herald must'nt even mention their names any more Of course the Herald ignored the gag, and just now one of the Austin doctors is in jail awaiting trial for manslaughter for causing the death of a married woman through an illegal operation The Herald, being a real newspaper, is giving the public all the facts and the medics are chagrinned, if that's spelled correctly"

UNIVERSAL

MILK MODIFIER

NON-FERMENTABLE

CARBOHYDRATE

A STANDARD PREPARATION recommended by Pediatrists for over a century Combines high solubility with comparative freedom from irritating fibre Subject to routine chemical, biological and bacteriological tests Packed in carefully sealed metal containers

Specially indicated for use in infant milk mixtures:

1. To modify the curd of cow's milk, thus increasing the digestibility of the protein and fat
2. As carbohydrate addition, to assist in the education and gradual development of an infant's Starch digesting functions, in cases of sugar intolerance where a less easily fermentable form of carbohydrate than the soluble sugars is called for, and in all instances where a pure form of Starch is required
3. As thickening agent in the preparation of thick cereal feedings, for cases of habitual vomiting, pyloric stenosis, etc

IN ADDITION Robinson's "Patent" Barley is largely recommended for administration as a bland, soothing fluid in the Anhydremia accompanying Infantile Fermentative Diarrhoea.

Samples and descriptive literature on request.

POST GRADUATE COURSE IN KENTUCKY

The Kentucky Medical Journal for June contains the following editorial on the Post Graduate Course sponsored by the State Medical Society

"The Post Graduate Course of instruction which we will have in Louisville from July 8th to 20th, inclusive, under the auspices of the State Medical Society, is rapidly taking shape, and we are anticipating a large attendance. The Louisville Tuberculosis Association has repeated its invitation to us to have luncheon and a series of demonstrations of all forms of tuberculosis This was an outstanding event during the last year's course The Children's Hospital will have open house with a luncheon such as was enjoyed before

"Although the course is held under the auspices of the State Medical Association, an invitation is extended to all the old graduates of the University and to all the doctors of the adjoining States to be with us at that time and partake of our hospitality A very pleasant feature of the course has been the meeting up with classmates The Louisville Baseball Club will be here most of the time so that on Saturday afternoon there will be an opportunity to see professional ball

"Begin to make plans to come to Louisville at this time as it will be a valuable review of new methods of diagnosis and treatment with plenty of variety so that the visiting doctors will be entertained as well as benefited"

If pure water is important to people in good health, how much more essential it is to invalids.

ROBINSON'S "PATENT" BARLEY & GROATS

These two old established preparations have held the confidence of the Medical Profession for years The Barley is mainly employed in infant dietetics, and for the quick preparation of pure Barley Water Robinson's Groats are largely recommended in conjunction with cow's milk for weaned infants, expectant and nursing mothers, and as an invalid diet.—See page XXV—*Adv*

AGAROL

Agarol contains no sugar—safe in diabetes, no alkali—does not interfere with digestion, no excess of oil—to cause leakage. Just the right proportion of ingredients to afford these desirable actions Softening of the intestinal contents, gentle stimulation of the peristalic function.—See page XXI.—*Adv*

FELLOW'S SYRUP

The after-effects of illness are often more serious than the disease itself. Fellows' Syrup of the Hypophosphites accelerates convalescence, restores energy and vitality Samples and Literature upon request.—See page XV—*Adv*

MEAD'S DEXTRI-MALTOSE

There is a unanimity of opinion among physicians upon the use of Mead's Dextri-Maltose.

It is shared alike by the pediatrist whose practice is confined exclusively to the feeding of infants, and the general practitioner whose work covers a multitude of different cases

An abundance of clinical evidence has proved it is well tolerated, easily assimilated and generally productive of satisfactory results In combination with various cow's milk and water modifications it has probably *successfully* been used to feed more infants than any other carbohydrate offered the medical profession.

A few infants can tolerate *any* carbohydrate. But *any* carbohydrate can not be fed all babies under all conditions. Sample and literature on request.—See page XXXII—*Adv*

AURORA HEALTH FARM

A new addition to the AURORA HEALTH FARM has just been completed, and this time it is an altogether modern building with elevator service from basement to roof, private bath and telephone in each room, a large, sunny dining room overlooking a magnificent panoramic view of the surrounding hills, a beautiful big lobby with adjoining porches that invite relaxation, and amusement rooms for indoor games in general

The purpose of this institution will continue to be the care and treatment of metabolic and cardio-vascular disturbances in ambulant patients, and for this purpose facilities for physiotherapy

PIGMENTED GROWTHS OF THE SKIN, THEIR SIGNIFICANCE AND TREATMENT*

By A. BENSON CANNON, M.D, NEW YORK, N Y

A WHITE man, 27 years old, whose only complaint was multiple painless nodules on the skin, was referred to me for diagnosis Six weeks before, he had noticed an almond-sized lump on the left shoulder which was followed in rapid succession by numerous other nodules over the trunk and extremities He had had gonorrhea and a chancroid three years previously

He was a well nourished and developed man, apparently in good health Over the body and extremities, most marked on the trunk, were numerous nodules varying in size from 0 75 to 2 5 cm in diameter Some were subcutaneous, the skin being freely movable over them, while others were attached to the skin, and some were intradermal growths of a slightly bluish tinge They varied in consistency from a moderate firmness to a stony hardness, and were non-tender to pressure The subcutaneous lesions often occurred at regular intervals and in line, giving the impression of following the lymphatics (Fig 1) The superficial glands, liver and spleen were not enlarged The heart, lungs, neurological and eye examinations were negative The blood count, Wassermann reaction and urine analysis were negative A nodule removed from the skin over the abdomen showed, on microscopic examination, melanocarcinoma About three weeks after the first physical examination I was able to see on the scalp, owing to a very close hair cut, a dime-sized ulcerated lesion just above the left ear, having the appearance of a mole. This, the patient said, was due to his physician's attempted removal of a mole by cauterization six months before Previous to my discovery of the mole he had steadfastly denied ever having had a growth of any kind removed A biopsy report of the lesion showed a malignant pigmented mole

The patient failed very rapidly after the appearance of the skin lesions The tumors increased in size and number, the liver and spleen became slightly enlarged, he lost weight and strength, and became pale Melanin was present in the urine only during the last ten days that he was under my care Death occurred about two months after my observation of him was terminated by his leaving for his home in Denmark Ten months had elapsed between the cauterization of the mole and the fatal outcome Had the mole been thoroughly removed at the time of cauterization, how many years of life could this man have expected?† (Fig 2)

FIG. 1

Showing pigmented and non-pigmented metastatic melanocarcinomatous nodules of the skin

Because of the very common occurrence of moles and other skin blemishes and their occasional termination in cancer there is oftentimes much confusion in the minds of the laity as to the significance of the several types This apprehension is frequently shared by the general practitioner and not infrequently by the dermatologist, especially where certain kinds of nevi are encoun-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Albany N Y May 23 1928

† Note Case No 1 previously appeared in *The Southern Medical Journal* Vol XX Feb 1927 No 2 pp 141 147

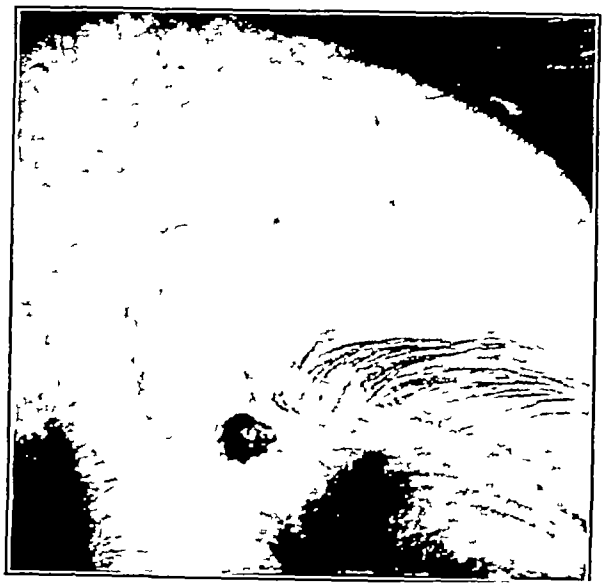

FIG 2

Pigmented mole which has begun to grow Note the irregular shape and surface markings This mole was removed four and one-half years ago No recurrence

tered Every few days we are asked it a certain type of skin growth should be removed and if so, how, and with what results Below, in a general sort of way, I am assembling my observat ons from studying and removing the variou s types of pigmented lesions

The most prevalent type of mole is the soft white or light brown colored pigmented mole Next in frequency one finds the dark, uniformly brown pigmented soft mole (Fig 3) The patient usually wants these blemishes removed from exposed parts such as the face, neck, shoulders and arms for cosmetic results, or from other locations where they are apt to be frictioned by the clothing or cut during shaving or scratched while combing the hair While it is possible for such nevi to become carcinomatous when subjected to prolonged irritation, such instances are exceedingly rare, and I believe never occur after the mole has been thoroughly removed I do not think that the deeply pigmented mole is more likely to become malignant than the lighter one Dr J A Fordyce, J A M A, p 91, Jan 8, 1910, stated that he thought the importance of pigmented moles had been exaggerated, that few had become malignant It has been our practice for many years to take off such moles with the electric needle, either by desiccation or by electrolysis and although I recall two people from each of whom we removed more than a hundred moles, I do not know of an instance where the patient has subsequently developed a melanocarcinoma It was Dr Fordyce's custom to treat each mole for two or more times, believing that in this way less scarring was produced

The light to dark brown colored, verrucous mole while not so commonly seen as the above types, also very rarely becomes malignant I saw a man 64 years old, a few days ago, in consultation with his physician for an opinion as to the advisability of removing a dime-sized uniformly dark brown colored verrucous mole which had been present without noticeable change in character ever since he could remember Twelve years ago he had consulted a number of very able dermatologists in regard to the same question, most of whom advised immediate and wide removal Two days before he consulted me he was again advised to have wide excision with serial sections made of the nevus It is interesting that most of the dermatologists whom he consulted expressed the opinion that once a mole showed evidence of activity or growth regardless of the way it was removed that a metastasis was quite certain to occur I told him I believed that if such a nevus had been present for 64 years without physical change and was located where it was not likely to be irritated that he could feel reasonably safe in leaving it alone On the other hand, there was very little likelihood that the nevus would recur or become malignant should it be thoroughly removed (Fig 4)

Seborrheic warts and senile keratotic lesions, particularly when brown or brownish black in color, are apt to be mistaken for pigmented nevi I have in mind an elderly physician who was warned not to have the brown keratotic warts and spots, which were so objectionable to his wife, removed from his face for fear of resulting melanocarcinoma Such lesions, as you know, are often the site of basal and sometimes prickle cell epithelioma but never melanocarcinoma (Fig 5)

Nevi with and without hair from light to dark

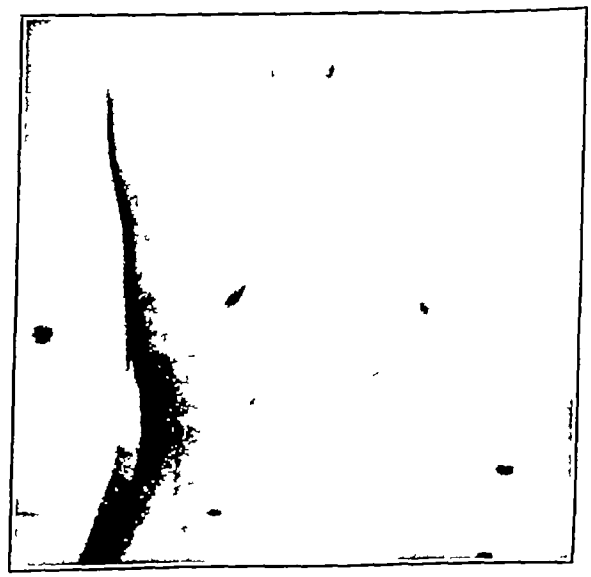

FIG 3

Dark brown pigmented moles

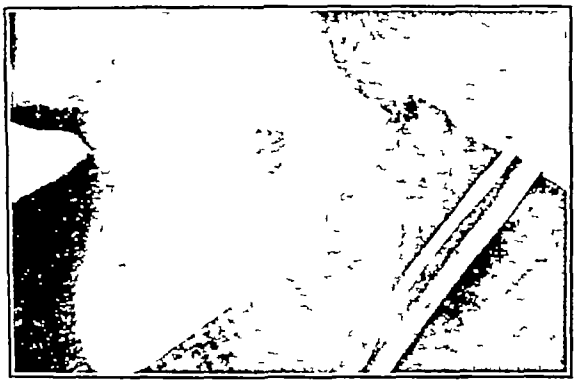

FIG. 4
Showing pigmented, congenital, verrucous nevus

slate or bluish black color occurring in all sizes from that of a split pea to that covering the greater portion of the trunk are not apt to become malignant. Such lesions may safely be removed with the desiccating or electric needle, excised, or even be treated with CO_2. Many dermatologists used to think it advisable to epilate the hairs of the nevi with the electric needle and destroy the remaining portions of the nevus later. Another method long used was one of repeated transverse puncture and electrolysis. So far as I can learn no serious results followed any of these procedures, so one might conclude that such nevi rarely ever develop into malignant growths even after such repeated irritation. (Figs. 6 and 7.)

One often sees dark bluish colored, pin head to large pea sized macular or very slightly raised

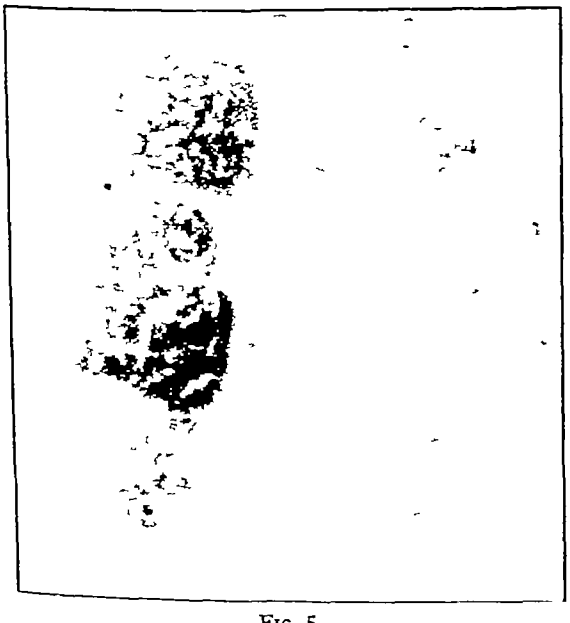

FIG. 5
Pigmented seborrheic warts on the back near the left shoulder

FIG. 6
Pigmented hairy nevus in girl of 12 years, showing the distribution

nevi which have been present from birth. Such nevi, I believe, seldom give rise to a malignancy. They can be left alone or safely removed with the actual cautery, desiccation, excision, or with the skin punch. Professor Krenn of Vienna has a small skin punch attached to an electric line such as dentists use, and by a rotary movement punches out these lesions with various sized drills, leaving the wound to granulate. I heard him say that he had neither seen nor heard of a melanocarcinoma following the removal of such nevi.

Any acquired type of nevus, papular or nodular, pin head to small marble size, bluish purple to brown black developing at any time during life, especially after the patient has reached the age of 30, should be regarded with great suspicion as those growths are frequently forerunners of carcinoma. Oftentimes such lesions

FIG. 6a
Enlargement of the center of the nevus, showing hair

have fine spider-like lines radiating from a central papule In several such lesions that I removed with the endothermic knife I was able to trace the lines of pigment for some distance from the central lesion along the deep cutis When these nevi are small, they are often mistaken for comedones and squeezed or picked with a needle, a thing which most often results in rapid enlargement of the black papule A young woman 28 years old consulted me 1½ years ago for a black papule the size of a No 6 shot on the left cheek, of six months' duration, which had gradually increased in size Thinking it a blackhead, she picked it with a pin and pressed the lesion between her finger nails When seen twenty-four hours later the central brownish blue papule was surrounded by an areola of redness and infiltration the size of a twenty-five cent piece which could be easily picked up between the fingers She was given a soothing lotion and when she returned four days later the swelling and redness had disappeared and only the dark papule remained This we removed with the endothermic knife, using a wire loop As nearly as I can judge the majority of melanocarcinomas occurring on the mucous membranes of the mouth and genitals originate from this type of nevus, and they not infrequently have their origin in the skin (Figs 8, 9 and 10)

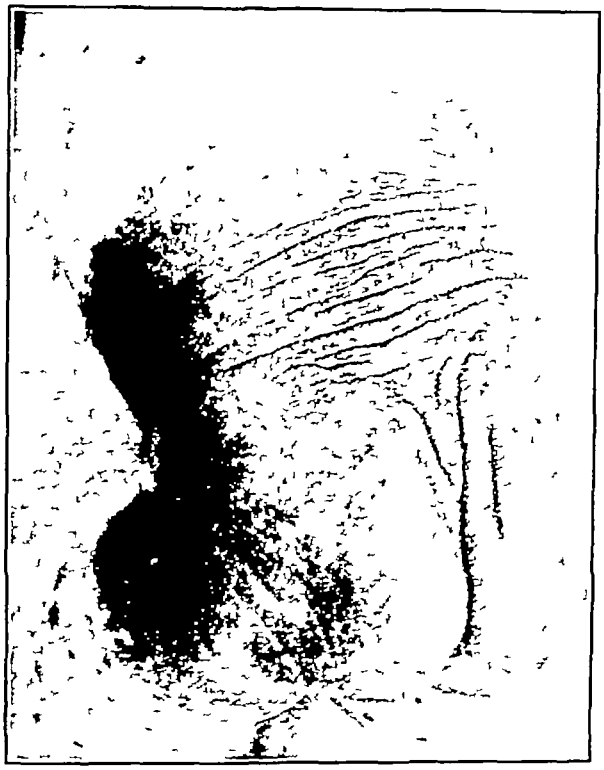

FIG 7

Congenital bluish black nevus in a child age 22 months

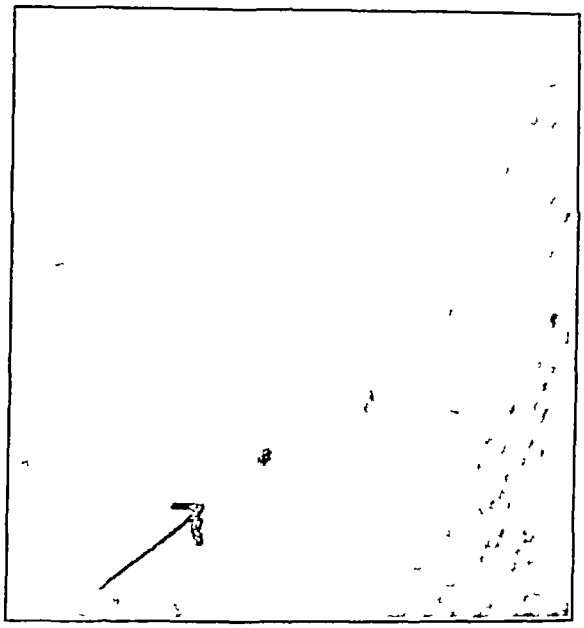

FIG 8

Showing an acquired, pin head sized, papular, pigmented nevus

Still another type of nevus which is prone to become malignant is the brownish or bluish mottled, slightly raised plaque often varying in size from a split pea to 1″ or 2″ in diameter This plaque not infrequently becomes verrucous over one part Such lesions are always dangerous and should, I believe, be thoroughly removed Not infrequently a malignancy will

develop in the pigmented area as illustrated by the accompanying picture (Fig 11) The following cases are illustrative

CASE REPORT

Case 2 I saw Mr J D, age 54, with Dr J A Fordyce in December, 1922 He had a dark colored growth over left side of forehead at edge of hair of six months duration When he first noticed it, the lesion was a dime-sized, dark brown to bluish colored elevation and it had since gradually increased in size His general health was good with no loss in weight Past and family histories were negative

Examination showed an elevated wedge shaped lesion about 1½" x 2" in diameter occupying the left side of forehead and scalp just in the middle of the part of the hair The base of the wedge was ¾" in diameter, bluish brown in color, warty, and surrounded by salt and pepper like, stellate nodules from the size of a pin head to that of a millet seed

It was diagnosed as beginning melanocarcinoma We widely excised the lesion with the endothermic knife from 1" to 1½" beyond the border, the flap about 4½" x 3" in diameter was lifted off, and then the base and edges desiccated Microscopic sections of the central part of the growth showed melanocarcinoma

The wound gradually healed by granulating, the patient gained in weight, and is living and perfectly well today For several years his urine was examined at repeated intervals for melanin and gave a positive reaction only twice, one week about six months after excision of the growth There were four smooth, elevated, pea sized, bluish colored nevi on other parts of the body

CASE REPORT

Case 3 Mrs E M, age 59, consulted me in April, 1923, complaining of a bluish colored growth on the outer surface of the right arm of one year's duration Lesion had begun as a small black dot, gradually increasing in size Her general health was excellent with no loss in weight. Family and past histories were negative There were no other lesions on the body except for occasional brownish soft moles

Examination revealed a dark bluish brown colored, elevated, smooth growth on the outer and upper third of the right forearm about the size of a twenty-five cent piece The lesion was widely excised 2" beyond the border of the lesion Pathological report of sections showed melanocarcinoma The wound granulated leaving a smooth, white, depressed scar No melanin was found in the urine at any time Patient is living and well today with no evidence of recurrence

CASE REPORT

Case 4 Mr J McG, age 66, consulted me on February 20 of this year, complaining of a growth on the outer side of the right thigh just above the knee of one year's duration He had had a flat, dark colored, raised, dime-sized plaque at the site of the growth as long as he could remember During the past year

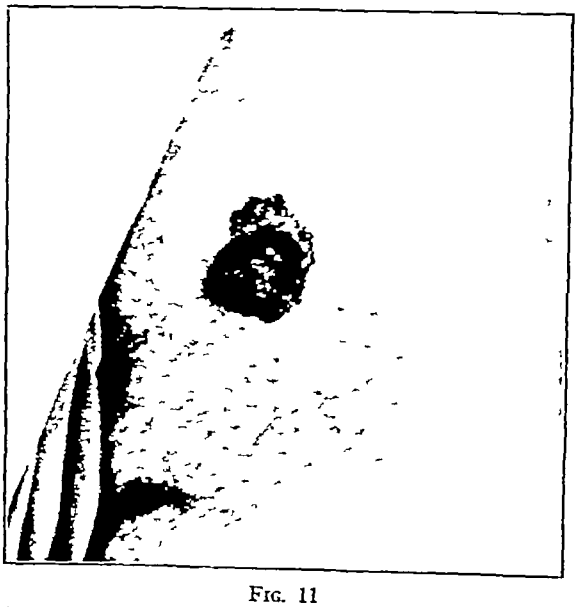

FIG. 11

Melanocarcinoma of 1 year's duration on a congenital melanotic nevus plaque

have fine spider-like lines radiating from a central papule In several such lesions that I removed with the endothermic knife I was able to trace the lines of pigment for some distance from the central lesion along the deep cutis When these nevi are small, they are often mistaken for comedones and squeezed or picked with a needle, a thing which most often results in rapid enlargement of the black papule A young woman 28 years old consulted me 1½ years ago for a black papule the size of a No 6 shot on the left cheek, of six months' duration, which had gradually increased in size Thinking it a blackhead, she picked it with a pin and pressed the lesion between her finger nails When seen twenty-four hours later the central brownish blue papule was surrounded by an areola of redness and infiltration the size of a twenty-five cent piece which could be easily picked up between the fingers She was given a soothing lotion and when she returned four days later the swelling and redness had disappeared and only the dark papule remained This we removed with the endothermic knife, using a wire loop As nearly as I can judge the majority of melanocarcinomas occurring on the mucous membranes of the mouth and genitals originate from this type of nevus, and they not infrequently have their origin in the skin (Figs 8, 9 and 10)

FIG 7

Congenital bluish black nevus in a child age 22 months

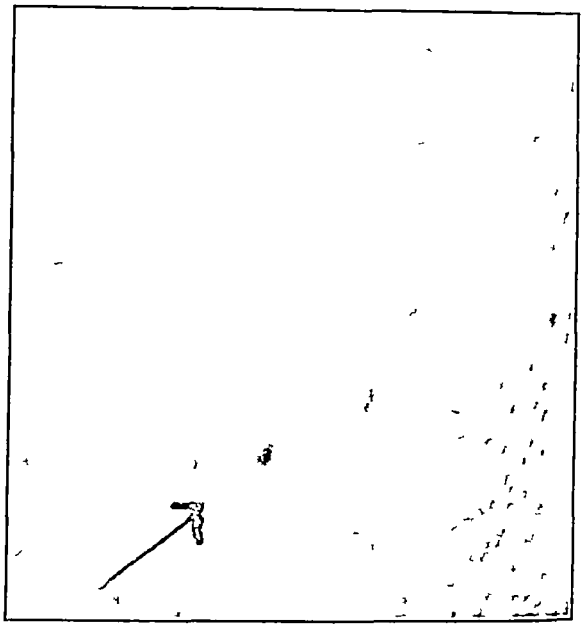

FIG 8

Showing an acquired, pin head sized, papular, pigmented nevus

Still another type of nevus which is prone to become malignant is the brownish or bluish mottled, slightly raised plaque often varying in size from a split pea to 1″ or 2″ in diameter This plaque not infrequently becomes verrucous over one part Such lesions are always dangerous and should, I believe, be thoroughly removed Not infrequently a malignancy will

FIG 9

M L, age 65, with melanosarcoma on cheek, with melanotic pigmentation of the skin on chest Died 5 years after picking a pin head sized, black dot on cheek which had gradually increased in size

Six of this number are dead, death having occurred from 10 months to 4 years after the first evidence of malignancy The other cases have been under observation for from 4 months to 6½ years, and only one of this number has shown any evidence of a recurrence, that of a young girl who had a melanocarcinoma removed from the conjunctiva of the eye followed 2½ years later by a melanotic nodule on the skin between the eyebrows

It is often exceedingly difficult to determine clinically or even histologically whether a particular type of melanotic growth has become malignant, or whether if thoroughly removed, there will or will not be a recurrence I believe that it is generally conceded that if a pigmented lesion, whether of the acquired or congenital type or a dark pigmented mole, has begun to grow and to show change in color, ulceration, irregularity in shape, or surface markings, a malignant change is probably taking place. By adding to the clinical evidence that of a pathological study where the sections show an irregular, downward growth with separation of the basal layer and perivascular and interstitial edema, a round cell infiltration and the formation in alveolar arrangement of pigmented nevous cells which are irregular and swollen, and the finding of some of these cells in the perivascular and interstitial spaces of the cutis, we can assume the presence of a malignant change The difficulty of establishing a diagnosis of a section from a melanotic growth is illustrated in two of the cases that I am reporting, one being that of a metastatic nodule removed and submitted to the pathological department of one of our larger institutions with the report that there was not sufficient evidence to make a diagnosis of melanocarcinoma Another similar nodule which was removed from the same man and submitted to the same pathologist showed all evidences of a metastasized melanocarcinoma. The other case was that of a section of a melanotic growth taken from the eye and shown to a number of the leading pathologists of America and Europe with a division of opinion as to whether the growth was malignant or a nevus I believe that if sections of a melanotic growth show the same type of structure and tissue reaction as that encountered in sections taken from a known case of melanocarcinoma that we can usually feel fairly certain that the case under investigation is one of melanocarcinoma

A hemangioma undergoing fibrous change is oftentimes very difficult to distinguish from a melanocarcinoma as illustrated by accompanying photographs (Figs 12 and 13)

Showing that the pathological picture of melanocarcinoma is variable Pierre Mason in Chapter X of "Tumeurs des Tissuo Pigmentaires" says that in spite of wide distribution melanotic tumors have common characteristics, but they have not the same histology Some resemble sarcomas, while others epithelioma. Usually they present a complex structure, sarcomatous on one side and epitheliomatous on the other, there being no sharp division between the two

Henry K Gaskel, *J A M A*, 60 341, Feb 1, 1923, states that nevi from which melanocarcinoma are apt to occur should never be disturbed unless there is slight irritation or signs of ulceration or degeneration. When this takes place wide

FIG. 12

Acquired traumatic hemangioma—lesion had developed following the squeezing of a blackhead six months previously and gradually increased in size, was bluish in color and firm on pressure Section of growth showed angioma

and deep excision is the only thing to be done. He advises the removal of pigmented moles when located where there may be irritation from ill fitting shoes, clothing, x-ray, or shaving, as they often cause speedy death He further states that any irregular in outline or waxy, smooth, with frequent little elevations, dark purplish in color should be regarded with suspicion He found the most common situation was the eye, face, extremities, especially the foot

The origin of melanin has long been a matter of controversy and is closely correlated with the question of the origin of nevus cells Von Recklinghausen's view, "Uber die Multiplen Fibrome der Haut," 1882, that a mole was a lymphangiofibroma was accepted until 1893 when Unna advanced the theory of epithelial origin. This theory has had many supporters, notably Bruno Block who, by the development of the dopa reaction, has indicated the site at which melanin is found K Kissmeyer, "Studies of Pigmentary Nevi in the Human Skin," working in Copenhagen with the dopa reaction attempts to prove

a nodule had developed in the center of the plaque which had gradually increased in size and frequently bled All his life he had had two other similar bluish colored plaques, one on the left thigh and the other on the outer left side of base of neck, which had shown no tendency to grow He had lost one sister with melanocarcinoma

Examination revealed, on the outer and lower aspect of the right leg just above the knee, a purplish brown colored nodule 1" x ¾" in diameter and ½" high, oval in shape, resting in the center of a smooth, slightly raised, brownish purple colored area about ¼" to ⅜" wider than the central mass On the anterior surface of the left thigh was a pea sized, macular, pigmented area at the left side of which was a large, brownish and bluish colored, warty lesion 1" x 1" in diameter

Treatment consisted of wide excision with the endothermic knife, the excision going about 1½" to 2" beyond the margin of the pigmented area It healed by granulation with formation of a smooth, depressed, white scar Biopsy of the nodule disclosed melanocarcinoma Urine has been negative so far and there has been no evidence of a recurrence

Case Report

Case 5 Mr L P, a young white man, age 28, seen in October, 1923, had a black, elevated spot on the outer surface of the left thigh This had begun about a year before as a small split pea-sized, black spot and had slowly grown Past and family histories were negative

Examination revealed an elevated, irregularly shaped blue-black spot about the size of a twenty-five cent piece, the surface was uneven There was no glandular enlargement We excised the spot with the endothermic knife going 2" beyond the border of the growth The wound healed of granulation No melanin was found in urine at any time The patient is living and apparently well

While nevi may occur on any part of the cutaneous surface, mucous membrane or menînges and undergo malignant change, the majority of melanocarcinoma have originated from acquired melanotic growths, more often located on the extremities

In a review of 14 reported cases of melanocarcinoma in which the primary growth could be ascertained, there were 11 from the acquired type, 2 from a congenital nevus, and the other from a nevus on the scalp Five of these were on the feet, two on the mucous membrane, and the remaining seven on face, head, trunk or upper extremities The age incidence was from 2 years to 84, the average being 49 There were 7 of each sex The duration of life from the time the lesion showed signs of malignancy was from 4 months to 4½ years, the average being 2½ years Metastasis to the skin was present in only 3 cases, 2 showing generalized nodular growths and the other a diffuse infiltration of the skin over the lower extremity where the primary growth occurred There was no glandular enlargement in these cases, whereas it was usually found in those in which the skin was not involved

A C Broders and W C MacCarty, *"Surgery, Gyn and Obst,"* vol 23, p 28, July, 1916, in a report of 70 cases from the Mayo Clinic found no region of the skin predisposed to the formation of melanocarcinoma, but the lower extremities most frequently affected They believe that cases originating in the eye have a better prognosis than those originating in the skin or mucous membrane The average age of the cases they report was 49 years, the average duration of the lesion before examination, 11 years All of these cases were operated upon and 63% were dead one year from the date of operation, 86 8% had died 3 years after operation, and 13.2% were living 4 years after operation The general concensus of opinion puts the average duration of life after the onset of malignancy at about 3 years In exceptional cases the duration of life from the beginning of a melanocarcinoma is sometimes much less or much greater In one case death occurred four months after lesion was noted on the glans penis Whiteside, *"Boston Medical and Surgical Journal,"* Vol XCII, May, 1891, reports death in 6 months after the beginning of the primary lesion Dr J A Fordyce reports in *J A M A*, p 91, Jan 8, 1910, one case metastasized 10 years after the primary lesion in the eye, although he gives the average duration of life as 3 years J N Roy, *"Medical Record,"* Nov 2, 1927, Vol 72, p 730, reported a case in which a patient for 20 years previous to consultation had had a pigmented growth on the palate This had slowly enlarged for 12 years Patient was living at the time of report a year later

Of the 13 cases of melanocarcinoma that I have seen 4 were women and 9 men, the ages varying from 10 to 69 years, the average being 44 Ten originated from the acquired type of nevi, having been present for from 6 months to 15 years, the average for about one year, one came from a congenital nevus, and one from a brown mole, while the other one was thought to have been from a mole removed 4 years previously The locations were

quently in those countries where there is close contact between rats and humans, many cases have been reported from Japan Horder in 1910 mentions the first cases reported in British medical literature Since then a few cases have been reported in publications of England and Ireland but usually with rather scanty details Herzfeld and Mackie[3] of Edinburg, presented a very carefully worked up case in 1926 Up to 1915 there had been reported about 50 cases in the United States, since then much laboratory work has been done on the disease and quite a number of cases reported In 1924 Mooser[4] reported two cases, in 1925, Dembo et al[5] reported a case as did Monroe and Mooser[6], in 1926 Theiler[7] reported one case, Baker[8] three cases, Hennerich[9] one case, and Lanford[10] one case, in 1927, Foster[11] reported one case, Rubino[12] two cases and Bayne-Jones[13] one case

The disease is most commonly conveyed to man by the bite of an infected wild rat, more rarely is it transmitted by infected cats Mooser[4] in examining wild rats was able to isolate the casual organism of rat-bite fever in about five per cent of rats examined Other animals which prey upon rats may become infected and transfer the infection to man In the laboratory Theiler[7] has shown that white mice and rats may harbor the infection without symptoms whereas the guinea-pig develops pathological changes comparable with those found in man Mooser[14] found that rabbits may also be infected with the disease

The search for the causal organism of rat-bite fever went unrewarded until 1916 when Blake[15] isolated the streptothrix muris ratti and Futaki[16] found the spirochaete morsus muris While occasional investigators since have reported finding the streptothrix, the majority have considered the spirochaete as the responsible organism and the streptothrix a secondary invador The spirochaete is notoriously difficult to isolate which may account for many failures to prove this point However, the prompt reaction of the disease to the administration of salvarsan or one of the other arsenicals strongly suggests that the causal organism is a spirochaete

The first cases of this disease were reported from Japan but since then cases have been reported from all over the world More cases are reported from sea ports and coastal towns than from cities of the interior Most of the early cases occurred in adult males but of late there has been a great increase in the number of cases occurring in children

There is considerable controversy as to the pathological changes produced by rat-bite fever in the human Blake[15] found in the case from which he isolated the streptothrix an acute ulcerative endocarditis subacute myocarditis, interstitial nephritis and hepititis and hemorrhagic infarcts of the spleen Other investigators feel that these changes are not characteristic of rat-bite fever but are rather the result of infection with the streptothrix isolated by Blake So few persons die as a result of this disease that satisfactory pathological investigation of the disease in humans has not been accomplished The Japanese investigators with considerable experience report but minor pathological changes found in those dying of the disease

The symptoms of rat-bite fever are definite There is usually the history of a bite by a rat The wound caused by the bite commonly heals quite promptly and with no more than the ordinary local reaction During the prodromal stage symptoms not unlike those preceding typhoid may be present, such as malaise, weakness, indefinite aches and pains, etc After a period of incubation of from 10 to 28 days, changes take place in the wound and general symptoms appear The area about the bite becomes swollen and painful, the tissues take on a dusky red color, the wound looks as if it was going to break down and discharge The anxious physician is tempted to incise it but usually nothing but dark blood is obtained The regional lymphatic glands become swollen and painful and often lymphangitic streaks appear The delay in the onset of local wound signs is a point of differentiation between this condition and ordinary wound infection. The onset of local wound signs is often accompanied by a chill and this is followed by fever The temperature is commonly high, from 103 to 104, the fever may be of the remittent or intermittent type It is usually marked by exacerbations at intervals of 2 to 6 days unless influenced by treatment In untreated cases, the paroxysms may continue for weeks, in severe cases the fever may be continuous in type while in the mild cases there may be but a slight elevation of temperature. In some cases the fever will remit for long periods

The skin eruption which accompanies this condition is quite characteristic and was present in about two-thirds of the cases reported It makes its appearance with the onset of fever and then gradually fades only to return with each exacerbation The eruption is usually found on the extremities and trunk and consists of slightly elevated maculo-papules varying in size from 1 to 5 centimeters The eruption has a bluish red color when the temperature is at its height, between the bouts of fever, the faded eruption has a dirty coppery color

Urinary examination is commonly negative The appearance of albumin is usually interpreted as an unfavorable omen There is usually a slight leucocytosis and a mild secondary anemia Some observors have reported a positive blood Wasserman in these cases Bayne-Jones[13], although his patient did have a positive Wasser-

that the nevus cells are originating from the pigment forming epidermis cells, which give up their connection with the neighboring epidermis cells and are slowly eliminated from the epidermis into the corium

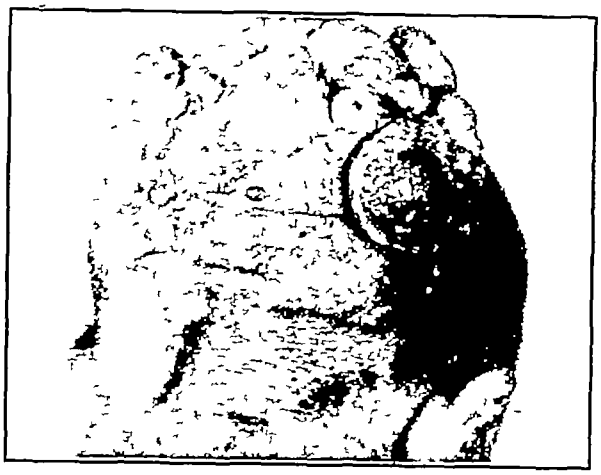

FIG 13

Child, age 4½ years, with gradually increasing nodular growth of the scalp since birth Originated as bluish silver dollar sized, soft angioma Ulceration and glandular enlargement, of 4 months' duration Had been diagnosed melanocarcinoma Sections of tumor showed fibroma angio-sarcoma while section of the glands revealed simple inflammatory condition Growth removed by Dr George A Wyeth with endothermic knife Child living and well

Thormahlen discovered that the urine of patients suffering from secondary melanotic cancer turned dark on oxidation I have repeatedly examined the urine for melanine in the cases of melanocarcinoma that I have had under my care and in only two instances was it present, the first being in case number 2, where it was found on two occasions six months after the melanotic growth had been removed It has not been present since, during a period of six years The other instance was found in case number 1 only in the terminal stage of the disease, a short while before death That the presence of melanine in the urine is not always evidence of melanocarcinoma is illustrated by the case of a woman 42 years old whom I saw 7 years ago suffering with a severe type of catarrhal jaundice, her trouble had been diagnosed as melanocarcinoma of the liver because of the presence of the melanine in the urine This woman made an uneventful recovery and is still living and well

Eppinger Biochem Zchrschr, 28 181, 1910, claims that the mere presence of a melanotic sarcoma, no matter how extensive, will not produce melanin unless the liver is extensively involved He argues that normal liver breaks down melanin that escapes into the circulation

J P Peters in *Arch Int Med*, November, 1923, Vol 32 709-717, "Melanuria Without Melanosarcoma," reported the case of a boy, age 13, suffering from cirrhosis of the liver and acites, who during life and at necropsy showed no evidence of melanosis, but whose urine contained large amounts of melanin

SUMMARY

1 Most people have congenital, soft, white, brown or black moles and sometimes verrucous, which are as a rule harmless and if removed thoroughly by any method do not give rise to carcinoma The same is true of pigmented, hairy nevi and the small, smooth macular, blue congenital nevus

2 The congenital nevi irregular in shape, color and surface markings and the acquired type occurring in the papular form are usually the types that give rise to melanocarcinoma, and should be radically removed with the endothermic knife as soon as they make their appearance, the wound being left open to granulate Where the lesion is removed early and thoroughly in this manner, I believe that there is very little likelihood of the development of a melanocarcinoma

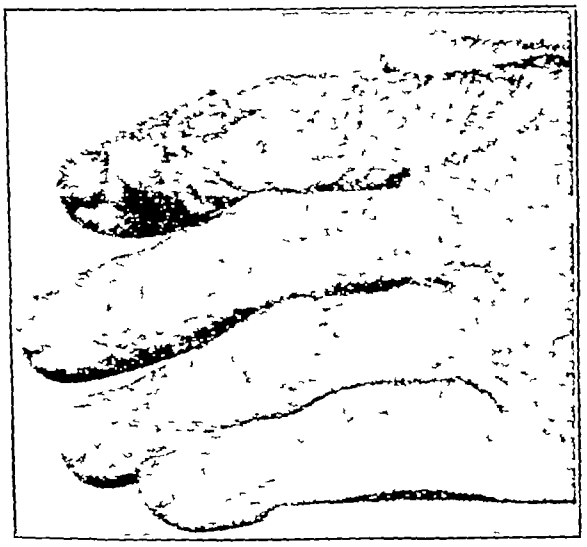
3 Any lesion that shows evidence of growth, change in color, surface markings irritation or ulceration should be immediately and radically removed

4 Of three cases of proved melanocarcinoma removed with the endothermic knife by wide excision of the growth and the wound left to granulate, there has been no evidence of recurrence in 6½, 5½ and 5 years respectively A fourth case in which a tumor was removed 4½ months ago is also free from evidence of metastasis

5 The average expectancy of life from the time a nevus begins to show evidence of malignancy is usually believed to be about three years In exceptional cases it varies from six months to twenty years

---

RAT-BITE FEVER REPORT OF A CASE



By ARTHUR M DICKINSON, M D, ALBANY, N Y

RAT-BITE fever is an infectious disease, following the bite by a rat and characterised by fever, typical eruption, involvement of the regional lymphatics and prompt response to arsenicals

The disease was apparently first reported in Japan where it was looked upon with as much fear as rabies formerly was in this country Wilcox[1] reported the first case in the United States in 1840 Miyake[2] in 1900 published the first detailed account of the disease Due to the fact that the disease is found more fre-

*Read before the Albany County Medical Society, February 13, 1929

perature rose to 102 8, the eruption appeared to be more marked than ever before. On August 3rd, forty-eight hours after administration of the arsephenamine, the temperature fell to normal for the first time since admission On August 4th, there was marked improvement in the patient's condition, he felt better and ate his food with more relish, the wound was healing and had a healthy appearance, the gland in the axilla was smaller and the eruption had almost disappeared By August 8th, the gland in the axilla was very small and not tender, the skin eruption had disappeared and the temperature

Showing rat-bite of index finger The characteristic skin eruption, though present, does not show in the photograph

still remained normal. The wound looked indolent and a slough was noted in it. The patient was discharged to his home at his own request. On August 16th, the patient visited me at the office He was feeling good, the wound was healthy in appearance, a very small gland was still palpable in the axilla, no eruption was noted On August 28th, I again saw the patient in the office and at this time the wound was entirely healed but the finger was slightly swollen One week later the patient was readmitted to hospital with an infection of the tendon sheaths of the flexor tendons of the right forearm There was no demonstrable source of infection Incision and drainage was followed by a very prompt recovery Cultures from the pus obtained showed a staphlococcus In October, some three months after I first saw the patient, he was again referred to me with fever and indefinite aches and pains but no eruption or signs of trouble with the finger Feeling that this was a fresh paroxysm of rat-bite fever, arsephenamine was advised but refused. Acording to a subsequent statement of the patient this attack lasted about eight days A recent report on the patient, seven months after he was first seen, states that he has been well since.

man reaction, introduces experimental evidence which seems to show that rat-bite fever does not give a positive Wasserman reaction

The spirochaete can occasionally be isolated from blood cultures especially if these are taken at the height of an attack of rat-bite fever In some instances the streptothrix described by Blake[15] is found More commonly the blood cultures are sterile The serum obtained from the wound will sometimes show the spirochaete as in the case reported by Dembo et al[5] More often the organisms are obtained by excising one of the skin eruptions and injecting this material into laboratory animals as done by Bayne-Jones[13] Herzfeld and Mackie[8] obtained the organism by innoculating the laboratory animals with material from involved glands As previously stated the isolation of the specific spirochaete is extremely difficult

The diagnosis will depend upon the history of a bite by a rat or other animal capable of transferring the infection, the appearance of the wound, the typical exanthem and the fever curve The proof of a rat bite need not be positive, we may merely suspicion it as did Baker[8] in one of his cases The prompt disappearance of symptoms upon administration of arsenicals is almost diagnostic The isolation of the spirochaete is not necessary although a quite proper refinement

Although a mortality of 10 per cent was previously assigned to rat-bite fever, this is much too high As a matter of fact the mortality should be almost nil with adequate treatment In the literature reviewed, Baker[8] reports the death of only one case and it does not seem that this is chargeable to rat-bite fever Infection with the spirochaete of rat-bite fever is considered so innoculous by Solomon et al[17] that they used it experimentally to replace the malarial treatment of paretics

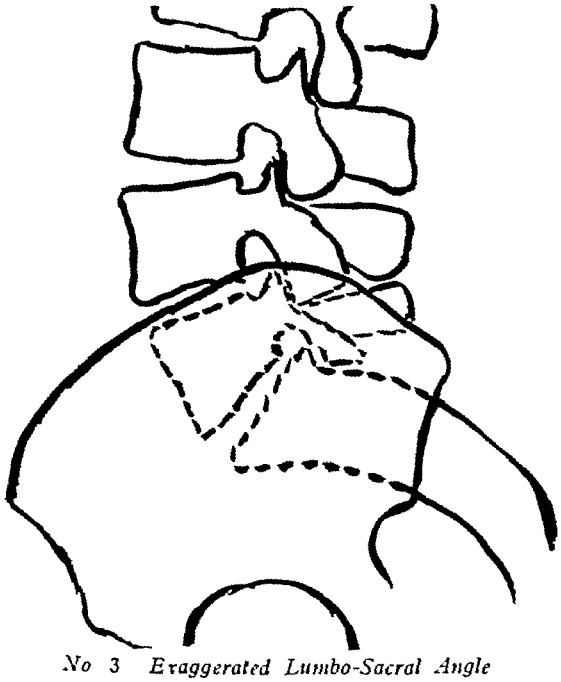
Rat-bite fever can be prevented by prompt cauterization of rat bites with carbolic or nitric acids After the condition is definitely established, salvarsan or one of the other arsenicals is indicated In many reported cases only one dose was required to kill the organisms, in some cases several doses were required

Case Report

V N entered the Albany Hospital, Albany, N Y, July 21, 1928, complaining of the left index finger He stated that on July 5th or 6th, while taking a rat out of a trap, he had been bitten on the back of the finger Following the bite, the wound bled freely and home remedies were applied The wound healed promptly and caused little inconvenience to the patient About 12 days after the patient had been bitten, the finger became red, swollen and painful The patient consulted a physician who incised the dorsum of the finger The physician informed me that he obtained about a teaspoonful of pus from the finger Because of persistence of pain and swelling, the patient was referred to me.

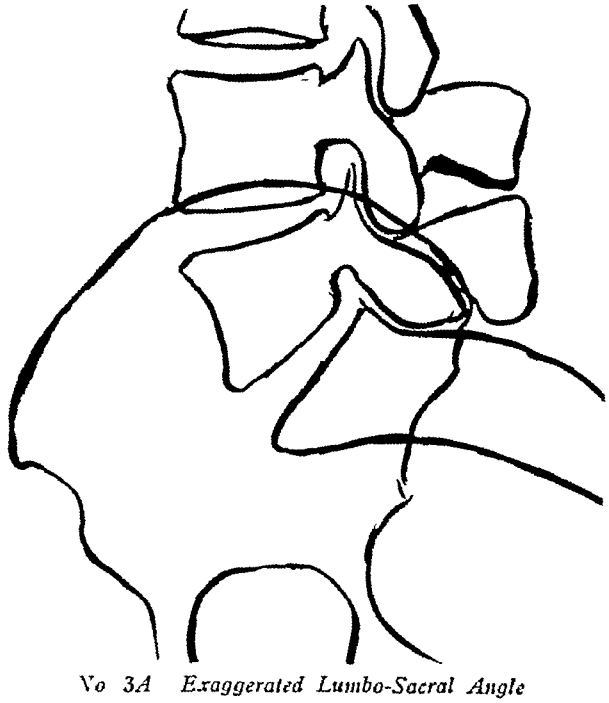
Upon admission to hospital, the condition was thought to be a simple infection of the dorsum of the finger, the finger was red, swollen and painful, the incised wound looked rather indolent, it was filled with a dirty grayish yellow exudate The temperature was 101.2, the urine was negative Bichloride hot packs were applied to the finger On the day following, there was noted no change in the wound or in the patient's general condition, the temperature went to 102 On July 24th, a blood count was done with the following report—rbc 4,200,000, wbc 7600, hgb 75% This day the temperature rose to 103 Under the impression that there must be some retained infectious material in the finger, it was incised under nitrous oxide anesthesia but no pus was obtained During the day, a tender gland about the size of a marble was found in the left axilla and there was slight enlargement of the epitrochlear gland There was tenderness along the course of the brachial vessels but no lymphangitic streaks were observed A maculopapular rash appeared on the left forearm, with a few spots on the dorsum of the hand and a few above the elbow None were observed on the rest of the body These maculo-papules were red or copper color and varied in size from 8 to 30 mm in diameter *X*-rays of the hand were negative for bone disease On July 27th, a blood culture was taken and reported negative The fever still continued as will be seen from the temperature chart There was little change in the local or general condition of the patient except that he appeared rather dull mentally By July 30th, there was a marked subsidence in the local symptoms, the finger was less swollen and painful, the eruption was beginning to fade and the gland in the axilla was smaller The temperature was still up to 101 however Saline dressings had been used on the finger for the past few days and a dark field examination was made of some of the exudate from the wound This showed no spiral organisms but did show many cocci and a few motile organisms Blood examination at this time was reported as follows rgc 4,600,000 hgb 80%, wbsc 8 200, differential count-polymorphonuclears 68%, lymphocytes 20%, mononuclears 12%, red cells normal The blood Wassermann was negative

By this time we felt that we were dealing with a clinical case of rat-bite fever although we had not been able to check the diagnosis by laboratory means On August 1st, the patient was given gm 0 4 sulpharsephenamine intravenously On this day the highest temperature recorded was 101 On the day following there was a marked aggravation of all symptoms The tem-



to hold it there. We see this in cases of infantile paralysis, with back and abdominal muscles affected Such a patient cannot pull herself up to an erect position, but, if you sit her up straight, she can often balance wonderfully well, though a very slight push will cause her to collapse

Just in case you think No 2 drawing is exaggerated, here is a tracing from a lateral *x*-ray of a lumbar spine (Nos 3 & 3a) Note the sharp curve, with the sacrum almost horizontal, and the pelvis tilted way forward, with the anterior superior spine pointing down toward the ground As you look at this tracing there seems to be almost nothing to prevent the fifth lumbar vertebra from sliding right off into the pelvis Only the articular processes seem to hold it in place That is quite true, with the assistance of a lot of good strong muscles and ligaments But, as the force of gravity acts straight down, and not around corners, there must be a lot of tension and strain on those muscles and ligaments In No 4 you see a more normal sacro-vertebral angle, pelvis more level, fifth lumbar less tilted forward, sacrum more vertical It seems to me self evident that less muscular effort is needed in this sort of position, than in that shown in No 3



What happens when any muscle is put under constant strain? It aches You have all experienced the effect of such strain at various times Most of the tall men among you probably come out of the operating room, after a long session, with a backache, especially if the table is a little low Why? Muscle strain, of course In the old days of clincher rims, changing a tire was one of the best ways of demonstrating postural backache you could wish for

The position of the body shown in No 2 is very often seen in people of middle age, and beyond, especially those who have not taken any pains to keep themselves in good physical trim Usually they haven't had time Too large a family to bear, and then to rear, with too little help But men are just about as bad, Most of our so-called "upstanding citizens", when you see them in the golf club locker room, or the YMCA Gym look exactly like this chap in No 2 drawing

There are, of course, a great many different types of people. There is the long thin type, so often associated with ptosis There is the short stocky type, and many intermediate The main trouble that students of posture have is in the fact that there cannot be any one normal for everybody There must be a normal for every body type The structure of the spine differs greatly In the tall, thin type, you will usually find lumbar vertebrae which look like those in No 5, another *x*-ray tracing Note the shape of these vertebral bodies Square, or somewhat taller than they are wide Now note another tracing (No 6) from an *x*-ray of a short stocky type These lumbar vertebrae are much wider than they are tall In this type of person you would not expect to find nearly as much normal flexibility of the spine as in the type shown in No 5 On the other hand this wide type can stand much heavier work, over a long period of years, than the more flexible sort In the less

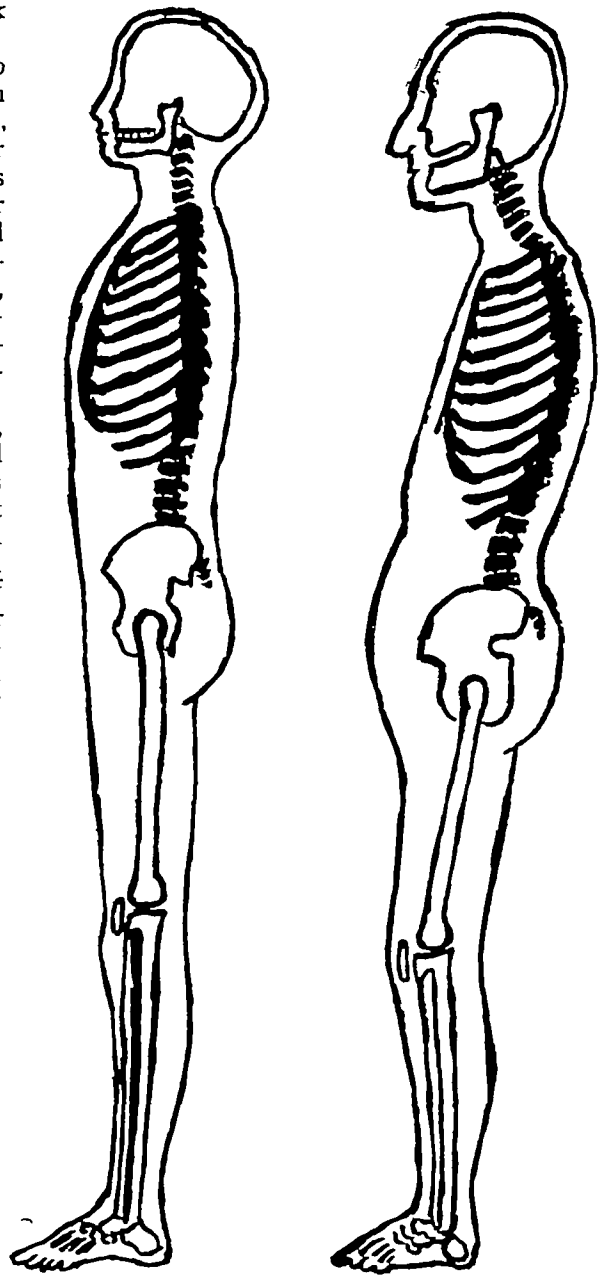
BACKACHE IN WOMEN, FROM AN ORTHOPEDIC STANDPOINT*

By CHARLES D REID, M D, SYRACUSE, N Y



MY reason for appearing before the section on Obstetrics and Gynecology with an orthopedic paper is, that I would like to discuss with you, for a few minutes, a type of case which is a familiar one in both your offices and mine, namely the woman with the low back pain

The time allotted to me will not allow me to more than mention most of the causes for pain in the lower back Pelvic inflammatory diseases, bad malpositions of the uterus, and many other conditions do, of course, cause pain, which is referred to the lower back Then, as other causes, we have trauma, causing fractures and sprains, malignant disease, congenital abnormalities, and last, but perhaps most frequent of all, the various types of arthritis In all such intra- or extra-pelvic conditions there is definite pathology to be found, and treatment aimed to remove such pathology will usually result in relief

The sort of case I want to discuss however, is that in which you can find little or no real pathology Your pelvic examination reveals nothing wrong, or nothing severely misplaced at any rate There is no history of injury, though almost anybody can think up some back strain or slight injury if they try Ordinary *x*-rays of the spine show no arthritis, or evidence of other trouble And yet the patient has a chronic backache She hardly knows what it is to have a day free from pain, yet she drags along, doing her work in some sort of fashion, which is not good for her, nor for her family, and calls for relief just as urgently as the most severe accident case

The answer to cases of this sort is to be found in bad use of the body mechanics This is something which any one of you can demonstrate on yourself, very easily Just recall the appearance of the spine, as seen in profile There is the slight forward cervical curve, the slight backward dorsal curve, the slight forward lumbar curve, and the more marked backward curve again over the sacrum The pelvis is level, the anterior and posterior superior spines just about the same distance from the floor The thighs are fully extended, and the knees straight Such a figure as is shown in No 1 schematic drawing Here you see the body weight is borne on the bony skeleton all the way to the ground When the body is in this position, all the muscles are concerned with is preserving the balance Practically none of the weight is supported by muscular action And if you recall, more than half of the body weight is above the waist

Now let the body assume a posture shown in No 2 drawing Here you see an exaggeration of every curve in the body Note the forward head, with increased cervical curve, the flat chest, with increased dorsal curve, the prominent abdomen, and especially the short sharp lumbar curve The pelvis is tilted forward, the sacrum is nearly horizontal There is no possibility of this body weight being borne in such a position without considerable constant muscular tension

No 1 No 2

* Read at the Annual Meeting of the Medical Society of the State of New York at Albany N Y May 22 1928

only examined a few hundred, but from those he has seen he expects to find practically the same percentage in bad posture, or about four out of five. That sounds very like the pyorrhea ads, doesn't it? And as he sees both girls and boys, you have a great many potential backaches now beginning in the schools in every city in the country

Now you will be getting ready to ask me why, if my figures are correct, we don't all have backaches all the time? Because we compensate for bad body mechanics just as so many people compensate for bad hearts for years without symptoms The potential trouble is there, and only requires the proper strain, or other stimulus, to begin to give trouble

Just a few words as to treatment It is really very simple in the majority of cases and yet very difficult. Which paradox is explained by an example or two Suppose a patient comes to you with some common complaint, a "cold," or a gastric disturbance of some sort After examination you give her a few directions as to diet, and so on, and a bottle of medicine to take three times a day, and she gets well—maybe as a result of your treatment, maybe not. Or you examine another and find that she needs an operation, She goes to the hospital, you do your stuff She lies in bed and is waited on, maybe for the first time in years, for a few weeks, and is well

In both these instances your patient is the passive recipient of your treatment She has had practically nothing to do herself But in these postural cases it is the patient who has got to make constant voluntary effort herself All you can do is show her how She must make a radical change in her habits of a lifetime, in standing, sitting, walking, breathing, and over a considerable period of time till she gets into correct habits Once she does it long enough to find out that it works, the rest will be easy, but it takes some time.

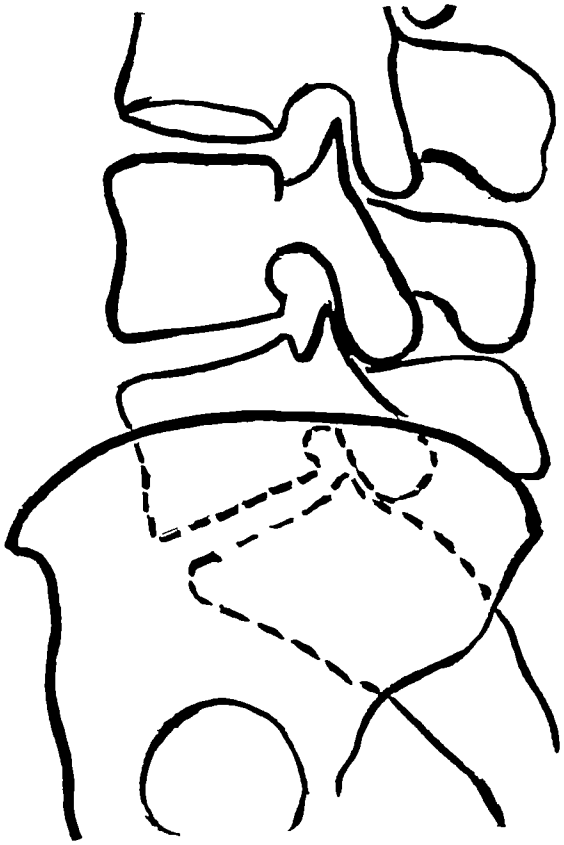
Don't expect to cure these backs with belts, braces, or any form of apparatus No splint ever cured anything yet All any splint does is prevent further damage, while some other means is curing the disability Put belts on your bad cases if you must, and they do help temporarily at times, but impress it on your patient that she has a perfectly good chance of getting permanent relief without the use of any apparatus for the rest of her life, if she will just put forth a little effort on her part, daily, for a reasonably short time, and "get the habit" of good posture.

THE RELATION OF ARSENIC TO PUBLIC HEALTH*

By C. N MYERS, Ph.D, and BINFORD THRONE, M D, BROOKLYN, N Y

Studies from New York Skin and Cancer Hospital.

THE deleterious action of poisonous plants and potions furnished prehistoric man with a weapon that inspired fear in the hearts of all who came within his reach These weapons were sometimes unscrupulously employed for criminal purposes, at others they were unconsciously employed medicinally In the latter case mystery and superstition gave rise to ideas of supernatural powers As old as poison lore, as insidious as poisons go, there has come down to us a substance that is now praised, and now decried but at times unsurpassed as a therapeutic remedy At the short time at my disposal it is impossible to go into a great many details, but a brief outline will be attempted



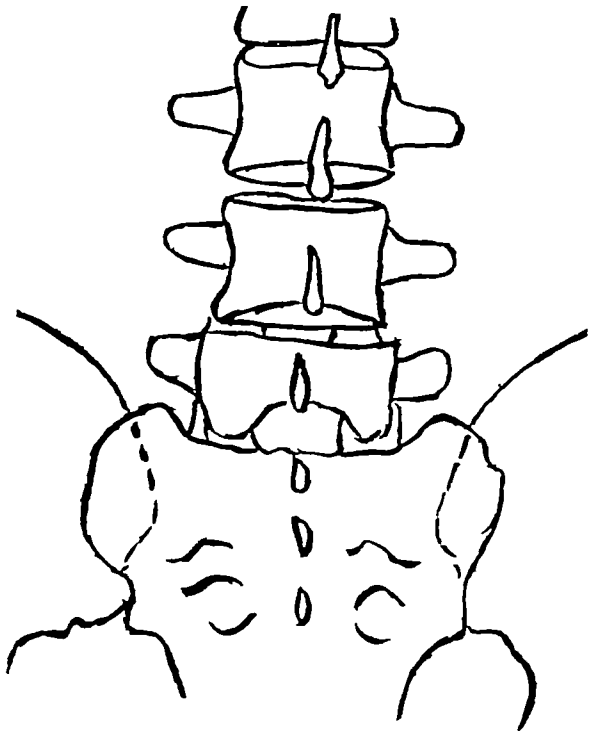
Arsenic and its effects have been so notorious that it has found its way into the literary achievements of learned people Arsenic on the one hand has been one of the most common and terrible poisons while under other conditions it is one of the most powerful and useful drugs In the days of Grecian achievement Hippocrates swore that arsenic should never be in the hands of the general public, yet at our present time it is seen in the hands and on the hands of a large number of clinical patients It might further be recalled that the early alchemist looked upon orpiment as the key to the Philosophers' Stone The relation of Geber and the early Arabian chemists is too well known to more than allude to the trisulfide, "white arsenic" and metallic arsenic in association with his investigations

The first direct evidence of arsenic as a poison for criminal purposes is found in the official record of the trial of one, a minstrel, Wondreton by name, in 1384 His attempt to kill Charles VI of France, his brother, two uncles, and others of the nobility has been referred to by us in previous publications As a lethal agent arsenic has probably figured more largely in history than any other poison The epidemic of poisoning that ran through France in the early part of the eighteenth century prompted the French Government to take drastic steps to stop it Arsenic probably has been the cause of more deaths known and unknown than any other one substance

Medicinally orpiment became official in sixteen of the pharmacopoeias of Europe during the seventh century Lanfranc's collyrium enjoyed two centuries of popularity as an application to ulcers Fowler's solution, Donovan's solution—Asiatic pills, atoxyl, arsacetin and the Salvarsans are other arsenical preparations that have maintained their popularity as therapeutic agents In this relation one must think of the element and realize its remarkable curative power Even under these

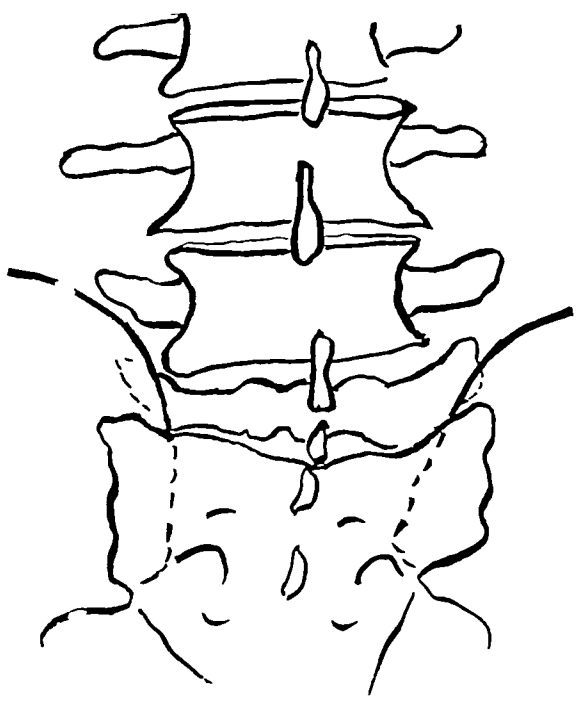
* Read before the Swampscott Meeting of the American Chemical Society September 12 1928.

flexible spines it follows that it does not take as much exaggeration of curves to cause muscular strain, as in the others Hence, before you make up your mind as to whether a patient is in very good, or very bad posture, you will probably have to get an x-ray of the lumbar spine, and deter-



No 4 "Normal" Lumbo-Sacral Angle

mine by it the type of back you are dealing with



Bad body mechanics does not begin suddenly in middle age or later, or at any definite milestone An orthopedic examination of school children is, in some cities, being initiated as part of the regular routine, and some surprising facts are being found Dr Lloyd T Brown,[1] of Boston, made an examination of the freshman class at Harvard, some years ago Seven hundred young men were examined Of these, only seven and a half percent, about fifty in all, were found to be in grade A posture. Twelve and a half percent more were fairly good That means that only one in five of a representative group of young men was in even reasonably good posture The rest were all bad, and about a hundred and seventy-five of them, or one in every four, was in grade D posture, like my No 2 drawing I haven't time to go into details of his findings, how so many of the grade D group complained of chronic backaches, even at that age, and so on

[1] Lloyd T Brown. Boston. *Med & Surg Jour* clxxxii. No 26 June 24, 1920

The orthopedist who is beginning a survey o Syracuse school children, gave me some very sim ilar figures He has no final statistics, as he has

No 5 Flexible Type

No 6 Strong Weight-bearing Type

the blood, urine, hair and milk from about 200 persons has led to the conservatively made statement that arsenic is found "normally" in a large number of persons, depending on the character of their food, drink, medication and environment. Under conditions of restricted diet, it may be entirely absent Some persons do not give a positive test at all times Recent chemical investigations show to some extent that all sorts of drugs and foods may be contributing factors in the detection of arsenic in human beings, the outcome depending on the methods of manufacture and the preparation of the foods Arsenic is almost invariably present, in varying amounts, in persons applying remedies containing ingredients contaminated with it to inflamed or ulcerating skin surfaces, and to a greater extent in persons receiving the element either by mouth, or intravenously, or connected with arsenicals in a preparative way At any rate, the latest analytic data, including such simple, every-day items as rhubarb and soda, sulphur ointment and sulpho-ichthyolate preparations as well as foods, in the list of "carriers" of arsenic, show that a careful history of the patient is requisite before arriving at a final decision regarding the meaning of the arsenic content of the blood, urine, or even the organs"

Later Cornwall and Myers showed that arsenic may pass from maternal blood to foetal blood and that even foetal tissues may take up arsenic, thereby proving that arsenic according to our present day artificial mode of living may be a normal constituent.

With these fundamental values in mind our interests are directed to the part that arsenic plays in the daily life of the average individual In general there are two types of individuals Those who are sick and those who are well, those whose resistance is so low that they are unable to resist the attack of the invading cause and are suffering with disease.

This briefly answers the question as to why some individuals suffer from poisoning and others are apparently temporarily immune Finding arsenic as a clinical entity in a large number of individuals immediately raised the question as to its source. Arsenic from a medicolegal point of view, and normal arsenic was discussed several years ago by one of us, and more recently by us in its relation to skin diseases, and internal medicine. It has been shown physiologically that arsenic is not a necessary constituent for the normal functioning of the tissues and that it acts as a stimulus to the involuntary nervous system and by prolonged action it paralyzes these functions, thereby resulting in dysfunction These clinical symptoms observed by us and the arsenic demonstrated in the blood and urine, are erythema, hemorrhagic and gangrenous processes, keratosis, leuconychia, leucoderma, pigmentation, scleroderma, universal psoriasis and psoriasis of the palms, eczema, peripheral neuritis, motor ocular paralysis, muscular atrophy, chloasma, and dermatitis exfoliativa These clinical symptoms may result from the use of amounts of arsenic many times less than the therapeutic dose and may appear several years after the initial exposure

These results have been confined by many independent workers and a report has appeared by Dr Carl Vogel of St. Luke's Hospital dealing in detail with this subject. As stated above, our investigations caused us to examine the blood, urine, and tissues of a great many cases and the finding of pathological amounts of arsenic in these specimens brought about additional studies on the source of the arsenic

It was earlier pointed out by us that arsenic is a contaminating substance in calamine and zinc lotion, ichthyol, rhubarb and soda, sulfur ointment and a variety of drugs taken internally Our attention was further directed to the subject of arsenic several years ago when certain abnormalities in the trypanosome equi perdum test suddenly appeared. Careful examination of the test revealed the fact that arsenic was present in the tissues of the rat thereby causing an arsenic resistance to this protozoal organism Examination of the food of the rat showed the presence of arsenic in the potatoes, and the canned tomatoes Examination of glucose used in supplementing the diet also revealed the presence of arsenic As soon as an arsenic-free diet was employed in raising the rats the test returned to its normal value Cotton from four different localities was obtained and arsenic varying from 0 0973, 0 578, 0 903, and 0 109 milligrams per 100 grams were found Our interest in this matter was brought about by the appearance of several patients handling cotton goods at the clinic showing typical arsenic symptoms Fruit handlers, tailors, electrotype workers, engravers, submarine workers, painters, physicians from an office recently decorated with green paint, insecticide workers, readers of the rotogravure section of the newspapers, children reared by artificial means, and individuals using tonics, tobacco smokers have represented the type of patients in whom arsenic has been detected

The therapeutic dose of arsenic trioxide is one-thirtieth of a grain, and that of sodium arsenate is one-twentieth, both according to the U S Pharmacopoeia After careful search in regard to the source of contamination it has been noted that peaches, pears, grapes, lettuce, celery, tomatoes, potatoes, cabbage and apples are the most common carriers among the fruits and vegetables Fish, lobster, and oysters among the sea foods, dextrose products, baking powder, cocoa, impure acid phosphate, cheap candy, and some baby foods, beer, wine, cider, moonshine were common articles of food and drink carrying undue quantities Elsdon of England found arsenic in 9 out of 51 bread wrappers The prevalence of arsenic in foods and beverages is widespread and the clinical symptoms are just as prevalent in these

circumstances occasionally severe disturbances are noted On the other hand our observations must be directed to healthy and diseased organisms for which arsenic is not specific and note its deleterious effects

European health authorities have ever been alert to this menace and our attitude in respect to its action has often led to the remark that America deals carelessly with the subject The beer cases in England (1900), the seventeenth and eighteenth century epidemic of poisoning in France, Gautier s work of 1899, Abel and Battenberg (1899) in Germany, lead the way in arsenic study in Europe The presence of arsenic in wall paper, and the investigations of Putnam and Hill at the Massachusetts General Hospital mark the early endeavor by American investigators in solving this problem

Before entering into this subject more deeply the critic immediately raises question as to what constitutes the fundamental basis for this subject —namely, what is the normal value and is there a normal value? Answer must be briefly made to this query Initially it should be stated that the reagents are carefully tested by blank determinations and in the amounts dealt with arsenic is absent. In the second place, reference is made to the original report of Gautier to the Paris Academy of Sciences in 1899 The Committee of the French Academy arrived at the following conclusions

"Speaking from a medicolegal point of view, I would state that arsenic, aside from the thyroid, mammary and thymus glands, never occurs in the human body except in the skin, hair, bones, milk and sometimes in the feces and then only in traces which are often infinitesimal Excepting the brain, the other organs and fluids, especially those forming the bulk of the body, as muscular tissue, liver, spleen, kidneys, lungs, blood, urine, etc., fail to show the slightest trace of arsenic
If a chemist therefore examines individually these arsenic-free organs by my method or by one less delicate and finds traces, especially appreciable traces, of this metalloid, such arsenic has been absorbed during life either medicinally or criminally"

In the editorial comment of the *Journal of the American Medical Association* the following appeared

'Somewhat less than a quarter of a century ago, the French chemist Gautier aroused considerable discussion in scientific circles by his communication to the Academie des Sciences of Paris on the occurrence of arsenic in the body He asserted that this element is a normal and consistent constituent of the thyroid, mammary glands, brain, thymus, hair, skin, milk and bones of man and various animals The quantities involved were very small, being at most less than 0 75 mg for each hundred grams of tissue. The content in the blood was almost infinitesimally small, not exceeding one part in fifty millions Gautier's statements were confirmed in a general way by a number of French chemists, but the quantities recorded by them were decidedly smaller

"Previous to this time the chief interest in the possible presence of arsenic in human tissues lay in its medicolegal bearings This subject was at one time an exceedingly "popular" poison, so that it figured prominently in many trials for murder The fatal dose is comparatively small, but since the methods of detection are very delicate, it has usually not been difficult to establish the presence of even minute amounts of arsenic post mortem in the organs when the use of the substance has resulted in death The finding of quantities approximating a lethal dose was the most important evidence that a prosecutor was wont to gather Great stress was therefore laid on the use of arsenic-free materials for embalming, and the chemist needed to be doubly cautious with respect to the purity of all chemicals used in his toxicologic analyses It is easy to appreciate, therefore, how disconcerting was the report, by a scientist of international repute, regarding the existence of "normal arsenic" in the body, even though the quantity was small at best There was, however, another aspect of possibly large significance attached to Gautier's comments In 1895, only a short time before the French communications were made, Baumann announced the discovery of small quantities of iodin as a normal constituent of the body, localized in the thyroid gland. With the rapid demonstration of the great physiologic significance of a few milligrams of a formerly unsuspected tissue component, it was a natural consequence that attention should be directed to the possible biologic importance of traces of other elements Copper and manganese were early taken into consideration, because of their widespread distribution in nature, and at this juncture came the announcement about arsenic.

The assumption that arsenic plays a part, as does iodin, in the functioning of certain tissues will be clearly negatived if it can be demonstrated that the former element is not a constituent of these tissues This is the outstanding problem of the physiologist. It does not concern the toxicologic expert, to whom it is immaterial whether minute quantities of arsenic in the body are normal or of fortuitous origin, so long as they are of a magnitude too small to have medicolegal significance. Of late, a new interest has been developed by the growing use of arsenicals in human therapy The problem of their action and distribution will be greatly confused if the drug administered is superimposed on quantities of arsenic, however small, which have an extraneous origin or a "normal" function This has been clearly recognized by Fordyce, Rosen and Myers at Columbia University, College of Physicians and Surgeons, as well as others, in their studies of arsenic as a remedial agent. An examination of

the blood, urine, hair and milk from about 200 persons has led to the conservatively made statement that arsenic is found "normally" in a large number of persons, depending on the character of their food, drink, medication and environment. Under conditions of restricted diet, it may be entirely absent. Some persons do not give a positive test at all times Recent chemical investigations show to some extent that all sorts of drugs and foods may be contributing factors in the detection of arsenic in human beings, the outcome depending on the methods of manufacture and the preparation of the foods Arsenic is almost invariably present, in varying amounts, in persons applying remedies containing ingredients contaminated with it to inflamed or ulcerating skin surfaces, and to a greater extent in persons receiving the element either by mouth, or intravenously, or connected with arsenicals in a preparative way At any rate, the latest analytic data, including such simple, every-day items as rhubarb and soda, sulphur ointment and sulpho-ichthyolate preparations as well as foods, in the list of "carriers" of arsenic, show that a careful history of the patient is requisite before arriving at a final decision regarding the meaning of the arsenic content of the blood, urine, or even the organs "

Later Cornwall and Myers showed that arsenic may pass from maternal blood to foetal blood and that even foetal tissues may take up arsenic, thereby proving that arsenic according to our present day artificial mode of living may be a normal constituent.

With these fundamental values in mind our interests are directed to the part that arsenic plays in the daily life of the average individual In general there are two types of individuals Those who are sick and those who are well, those whose resistance is so low that they are unable to resist the attack of the invading cause and are suffering with disease

Thus briefly answers the question as to why some individuals suffer from poisoning and others are apparently temporarily immune Finding arsenic as a clinical entity in a large number of individuals immediately raised the question as to its source Arsenic from a medicolegal point of view, and normal arsenic was discussed several years ago by one of us, and more recently by us in its relation to skin diseases, and internal medicine. It has been shown physiologically that arsenic is not a necessary constituent for the normal functioning of the tissues and that it acts as a stimulus to the involuntary nervous system and by prolonged action it paralyzes these functions, thereby resulting in dysfunction These clinical symptoms observed by us and the arsenic demonstrated in the blood and urine, are erythema, hemorrhagic and gangrenous processes, keratosis, leuconychia, leucoderma, pigmentation, scleroderma, universal psoriasis and psoriasis of the palms, eczema, peripheral neuritis, motor ocular paralysis, muscular atrophy, chloasma, and dermatitis exfoliativa These clinical symptoms may result from the use of amounts of arsenic many times less than the therapeutic dose and may appear several years after the initial exposure

These results have been confined by many independent workers and a report has appeared by Dr Carl Vogel of St. Luke's Hospital dealing in detail with this subject. As stated above, our investigations caused us to examine the blood, urine, and tissues of a great many cases and the finding of pathological amounts of arsenic in these specimens brought about additional studies on the source of the arsenic

It was earlier pointed out by us that arsenic is a contaminating substance in calamine and zinc lotion, ichthyol, rhubarb and soda, sulfur ointment and a variety of drugs taken internally Our attention was further directed to the subject of arsenic several years ago when certain abnormalities in the trypanosome equi perdum test suddenly appeared. Careful examination of the test revealed the fact that arsenic was present in the tissues of the rat thereby causing an arsenic resistance to this protozoal organism. Examination of the food of the rat showed the presence of arsenic in the potatoes, and the canned tomatoes Examination of glucose used in supplementing the diet also revealed the presence of arsenic As soon as an arsenic-free diet was employed in raising the rats the test returned to its normal value Cotton from four different localities was obtained and arsenic varying from 0 0973, 0 578, 0 903, and 0 109 milligrams per 100 grams were found Our interest in this matter was brought about by the appearance of several patients handling cotton goods at the clinic showing typical arsenic symptoms Fruit handlers, tailors, electrotype workers, engravers, submarine workers, painters, physicians from an office recently decorated with green paint, insecticide workers, readers of the rotogravure section of the newspapers, children reared by artificial means, and individuals using tonics, tobacco smokers have represented the type of patients in whom arsenic has been detected

The therapeutic dose of arsenic trioxide is one-thirtieth of a grain, and that of sodium arsenate is one-twentieth, both according to the U S Pharmacopoeia After careful search in regard to the source of contamination it has been noted that peaches, pears, grapes, lettuce, celery, tomatoes, potatoes, cabbage and apples are the most common carriers among the fruits and vegetables Fish, lobster, and oysters among the sea foods, dextrose products, baking powder, cocoa, impure acid phosphate, cheap candy, and some baby foods, beer, wine, cider, moonshine were common articles of food and drink carrying undue quantities Elsdon of England found arsenic in 9 out of 51 bread wrappers The prevalence of arsenic in foods and beverages is widespread and the clinical symptoms are just as prevalent in these

conditions as when arsenic is administered therapeutically or accidentally Our investigations show that there is no fixed quantity which will produce lesions, therefore no tolerance limit should be fixed It is absolutely impossible to determine beforehand whether a small dose—even infinitesimal in amount—will act as a fulminator in producing any one of the clinical symptoms previously mentioned All dynamite is potentially explosive—percussion of any type adds the necessary impetus Arsenic is exactly in this class in its relation to health Lead and copper also must not be overlooked but their discussion is extraneous to this report In our Clinic about 35 per cent of the cases with skin lesions of the eczema type are due to arsenic This does not include the large group of neurological cases that are gradually being classified, nor does it include that group of obscure cases coming into the hands of the Internist in which paralysed functions have been observed Dr W B Long who is associated with us has been able to reproduce skin manifestations by smoking cigarettes The presence of arsenic in tobacco was very ably worked out by Remington who reported his findings in the *American Chemical Journal* The presence of arsenic in these products enumerated is certain but its control is open to question

Recently the boll-weevil control has made use of the aeroplane, the anophelene larvicide control has also made use of this same method The public at large are submitted to this same arsenic action The use of insecticides combining copper, lead and arsenic is also a widespread source of contamination The public at large eat the fruits and vegetables The excretion of arsenic following the consumption of fruits, vegetables, and fish is markedly increased showing definitely that arsenic is passing into the circulatory system Death from chronic arsenic poison has been noted eight years after the exposure In our cases it is not uncommon to find clinical symptoms two to six years after the exposure Hills found arsenic present in the urine of 75 per cent of the specimens examined and attributed its presence to wall paper, and insecticides

Large expenditures of time and money have brought about widespread use of larvicides and insecticides, yet the public health has not been given adequate consideration due largely to the choice of the lethal agent Propaganda for the widespread application of these substances has resulted, followed by arbitrary methods of control based upon inaccurate tolerance limits In England 1/100 of a grain per pound and per gallon has been fixed arbitrarily to allow for the sale of these products It is our opinion that no arsenic should be present as contaminating factors in foods and drugs, that arsenic control is as important in vegetables as in fruits, that either fewer fruits or less perfect fruits are preferable to contaminated fruits It is our opinion that the future holds in store more drastic measures which will demand the elimination of arsenic as a contaminating factor and that arsenic and lead insecticides must be supplanted by safer agents It is too early to evaluate the total destructive influence of these substances on human health The time is not far distant when the importance of arsenic and its relation to health will be recognized and the regulatory procedures will be properly handled by the health service Furthermore the development of new destructive substances will demand a more careful study of health first and insecticide destroying properties secondarily

EPILEPSY AND THE CONVULSIVE STATE A CRITICAL RESUME WITH COMMENTS ON THERAPY*

By SAMUEL BROCK, M D, NEW YORK, N Y

FROM time to time, a critical resume of an unsolved problem in disease seems opportune Newer researches lead to newer theories or modifications of older ones, different physiological and pathological concepts are established, therapy becomes more rational and less empirical In the case of such a puzzling complex as epilepsy, one must ask the indulgence of the reader if many essential questions still remain unanswered, and if much that is well known is again presented in a different setting

For a number of years, it has been evident that epilepsy is not a disease sui generis but a symptom complex of a many-sided nature As a consequence, one began to speak of "The Epilepsies" Of late, however, the term, "convulsive state," has been introduced to replace the time-worn word, "epilepsy" with its traditionally restricted connotations

Types of Convulsions Mechanism

By the convulsive state is meant a paroxysmal disorder of clonic or tonic muscle spasm involving larger or smaller segments of, or even the entire body The resultant movement is an involuntary, disordered, utterly purposeless one, throwing the part, or the entire body out of normal into an abnormal posture Whether consciousness is or is not disturbed will depend upon considerations to be discussed later

In the idiopathic type of convulsive state (grand mal), three phases may be recognized in the order of their appearance, one—a fleeting flaccid stage during which the individual falls, two—the tonic phase, three—the clonic phase Quite rarely the attack may be limited to the flaccid stage in which the acute general loss of tone produces sudden "deposturing" or collapse The tonic stage with unconsciousness is due to suspension of cortical function, and the uninhibited activity of centers in the brain stem The succeeding clonic phase indicates return of cortical activity, even irritation The tonic and clonic stages may appear separately in man, and for the sake of clarity will be so considered in the following

The types of such seizures are (1) Tonic, and (2) Clonic. The tonic type is often seen succeeding the very transient flaccid stage of the so-called grand mal seizure, and is usually generalized Centers in the brain stem are functionally disconnected from the dominant cerebral cortex, and their uninhibited activity or their isolation results in a decerebrate rigid state Normally the inhibiting impulses are believed to be mediated by the fronto-ponto-cerebellar pathways (Weed Warner and Olmstead) The stimuli are transmitted from the brain stem centers to the final common pathway probably along so-called extra-pyramidal pathways This tonic state consists of a widespread spasm of the extensor muscles The head is retracted, the back arched, the extremities extended and adducted, the hands are pronated, the fingers are flexed, the feet are in equinus, the jaw is tightly closed (Sherrington, S A K Wilson) In man the upper extremities are usually flexed and the head and eyes turned to one side Consciousness is lost

The *constant* dilatation and fixity of the pupils, the early pallor succeeded by redness and cyanosis, the *occasional* loss of urine and feces, salivation and perspiration are phenomena of the grand mal attack referable to activity of the vegetative nervous system

The clonic or Jacksonian fit is due to irritation of the motor cortex of the brain, the abnormal stimuli are carried by the intact pyramidal tract to the lower motor neurone, thence by way of its final common pathway to the musculature If the focus of irritation spreads, then adjacent centers in the Rolandic area are affected in a very regular manner which is conditioned by their well-known anatomical juxtaposition The movements are interrupted, and frequently segmental When this type of convulsion occurs alone, consciousness is not disturbed, until the movement spreads from one half to the other half of the body

A spinal and bulbar form of convulsion is best seen in cases of strychnine poisoning Here there is anarchy in the realm of the lower motor neurones, and a toxic extensor spasm is noted, comparable in many respects to the above-described Consciousness is fully retained

A number of facts are known about the induction of the convulsive state in man and the higher mammals Yet we know of nothing introduced from without which will render man or animal subject to recurrent spasms Herein lies the great difference between exogenous convulsogenic agents capable of producing a *single* series of convulsions and the disease of man with its remarkable *tendency to paroxysmal repetitions* of the convulsive state The reason for this periodic recurrence is unknown It can hardly be explained by the assumption of any special theory When we know why the attacks are recurrent we shall have gotten down to a very fundamental element in the understanding of the disorder Collier believes that the periodicity and other facts argue strongly for a disturbance in metabolism, a "toxipathic" (i e a humoral factor) as the basic cause

Analysis of Convulsogenic Factors

If one analyzes the many factors involved in the production of the convulsive state, it becomes evi-

* Read at the Annual Meeting of the Medical Society of the State of New York at Albany May 23 1928

dent that they may be grouped under one of two headings—A Cerebral, B Humoral The experimental work of W E Dandy and R Elman illustrates this duality best If a normal cat be given absinth by mouth in sufficiently large amounts, convulsions will result This illustrates the operation of a pure humoral exogenous factor If now, one produces a lesion in the cerebrum of the animal, either by simple extirpation of the cortex and sub-cortex, or by simply placing a foreign body beneath the cortex, it is soon found that one-third to one-seventh the initial dose of absinth will be convulsogenic By injuring the cerebral tissue, a cerebral factor is introduced

In Table I, we have the humoral factors

TABLE I

Humoral Factors

I Exogenous	II Endogenous
1 Alcohol, lead (absinth, camphor—monobromate, santonin, picrotoxin, apomorphin, etc.)	1 Uremia.
2 Insulin (anoxemia ?)	2 Eclampsia
3 Alkalosis (due to hyperventilation)	3 Endocrine dyscrasias Hormonal Disturbances a. Parathyroid, b Thyroid, c. Pituitary, d Ovarian.
4 Foreign Proteins	4 Toxins of the infectious diseases in infants
	5 Spasmophilia.

The Humoral Factors

Among them, certain items deserve especial comment In rare instances, the individual may suffer from the convulsive state only when sufficient alcohol is imbibed Rosett in this country and O Foerster in Germany, have drawn attention to the effects of forced over-ventilation of the lungs In normal persons, tetanic features appear In 55 per cent of epileptics, the convulsive state is precipitated The alkalosis produced by the deep breathing seems in some way responsible for the attacks, possibly through the disturbance of the calcium ion balance in the blood (F Georgi) Fried and Frisch found an increased blood calcium in these cases The tetany so induced in normal individuals points to the parathyroid gland, and disturbed calcium metabolism In this connection, Geyelin, of New York has emphasized the beneficial effects of starvation on those afflicted with convulsions Work in Cobb's Laboratory in Boston, has tended to prove that the acidosis accompanying starvation is a factor in this prevention of convulsions Yet further work discloses that neither acidosis alone nor ketosis alone prevent seizures Furthermore studies in the acid-base equilibrium (v i) show that the formation of endogenous acids seems to be part of the critical physico-chemical change just preceding the convulsion

In agreement with the recent studies of the German school to be discussed below, is the work of the Italian investigator Cuneo, who believes that there is a disturbance in the starch metabolism resulting in the formation of certain acids (acetic, lactic, butyric, tartaric) Normally the liver and small intestine break these up into urea and sodium carbonate In epilepsy, they are found unoxidized in the urine Osnato, Killian and their co-workers have found increased lactic acid in the blood and cerebro-spinal fluid of epileptics in the interparoxysmal period An acidosis results, in the presence of which, the cellular nucleo-histon bodies split into nucleinic acid, and a convulsogenic proteose (The salts of the afore-named acids are also convulsogenic) Donath (quoted by Muskens) believes that in the convulsive state, alkaloid-ammonium compounds, fragments of normal metabolism, react on a nervous system, the threshold of which has been lowered by either hereditary, or congenital, or toxic, or infectious, or traumatic affections These compounds are trimethylamin, cholin, kreatinin, guanidine, and ammonium carbonate Except for the first (trimethylamin) Donath produced convulsions with these agents

A number of observers have studied the question of the split products of protein metabolism L M Wallis and W D Nicol (England) found that about 20 per cent of epileptics gave positive skin reactions They removed the offending proteins from the diet in some of these cases, gave others peptone by mouth, and reported good results Others, including J S Collier, were disappointed in the use of protein therapy In connection with anaphylaxis, V M Buscaino's work deserves mention On examining 396 thyroid glands he isolated an abnormal protein from the thyroid of 71 per cent of epileptics Abderhalden tests with the serum of epileptics reacted positively with the thyroid of epileptics much oftener, and more intensely than with non-epileptic thyroids In certain cases he regards the convulsions as an anaphylactic crisis [1]

In the group of endogeneous humoral factors, *the endocrine* dyscrasias are of especial interest. The role of the parathyroids in the convulsive state of tetany is well known In three cases of severe epilepsy, O Foerster implanted human parathyroid glands He reports unmistakably beneficial effects on the number and intensity of the convulsive seizures In regard to the thyroid gland, Buscaino's observations, above-mentioned, are of interest

Elsberg and Stookey showed that thyroidectomized animals are more susceptible to absinth in the production of convulsions The parathyroid glands may also have been injured in their

[1] The recent work of Lennox is of especial interest in this connection. He and his co-workers found an increased concentration of blood fibrin in 34 of 100 epileptics A possible relationship to abnormal protein metabolism and disturbed liver function is suggested by Lennox. He points out that the liver may have a so-called detoxifying function as shown by the fact that dogs in which an Eck's fistula had been produced when fed meat, may have convulsions.'

experiments The foregoing observations lend weight to the belief that the parathyroid and thyroid glands cooperate in rendering innocuous toxic convulsogenic elements (foreign protein split products?) in the blood stream (Timme, Zabriskie)

As regards the pituitary gland, two points deserve mention One is the frequency of signs of dyspituitarism (acromegalic features, or Fröhlich's syndrome), and sella turcica changes demonstrable by X-ray, in the epileptic. The other is the fanciful hypothesis in which the pituitary gland is believed to enlarge periodically in a sella too small for it. This results in a suspension of function of the posterior lobe which is said to produce an increase of general cortical irritability The nearby uncinate gyrus is pressed upon and is apt to be the initial explosive focus

Just what role the gonads play is difficult to say During the menstrual period and pregnancy, the seizures are often increased in number and severity

Concerning the *hormones*, Frisch classifies them as follows a. those inhibiting the convulsive tendency—parathyroid, pancreas, thymus, gonads and those thyroid hormones that accelerate protein and fat metabolism, b those promoting the tendency, adrenals and certain hypophyseal hormones and those thyroid hormones which stimulate the sympathetic, the adrenals and sugar metabolism He refers the convulsive tendencies of childhood, puberty, menstruation, pregnancy and the climacterium to upheavals in the hormonal status

Physico-Chemical and Metabolic Studies

The recent studies of de Crinis, F Kraus and Felix Frisch, especially the latter's stimulating monograph ("Das Vegetative System der Epileptiker," published by J Springer, 1928), show the remarkable, dominant part played by humoral processes in the idiopathic convulsive state Their researches in physico-chemistry (electrolytic and colloidal studies, etc) revealed new and striking facts which seem to point the way to the final elucidation of the great enigma I shall attempt a brief analysis of these excellent contributions Their studies emphasize the findings in the interval or *preparoxysmal* phases of the disease During the interval period, the vegetative nervous system shows a pathological lability, variability and responsivity, with no dominance of vagus or sympathetic innervation. The attack itself is associated with a state of sympathetic dominance.

In the sphere of metabolic activity they demonstrated remarkable findings only disclosed by *serial studies* Firstly, in the preparoxysmal phase, a *water* and *NaCl* retention were often found (associated naturally with oliguria and a gain in the patient's weight) Secondly, rare cases showed the above during the interval period with a relative water-NaCl diuresis just before the attack Thirdly, certain cases showed a retention of NaCl without a corresponding water retention in the tissues The first group is associated with a hypochloremia, the others by markedly variable blood chloride values

The other electrolytic constituents of the blood show considerable variations The blood calcium is under normal in the interval, and rises considerably above normal just before the convulsion, as shown by *serial studies* Potassium values vary greatly with no relation to the time of the attack Calcium and potassium are antagonists Calcium ion concentration leads to a splitting off of H (acid) ions, potassium to splitting off of OH (alkaline) ions Hence, calcium attracts the acid ions into the blood stream which leads to relative alkalinization of the tissue cells It is interesting to note that relative richness in calcium and magnesium diminishes the convulsive tendency of nerve centers, relative richness in potassium and sodium increases it This coincides with the retention of Na and the withdrawal of tissue calcium in the pre-paroxysmal phase Increased blood calcium has been found in eclampsia (Consoli) and during the menses A disturbance in the *acid base equilibrium* is present in epilepsy In the intermediate stages of metabolism endogenous acids appear which disrupt the alkali-CO_2 coalition This acidosis is manifested by—1 a reduced CO_2 combining power (de Crinis), 2 *a lessened alkali reserve* (determined by titration) i e *hypocapnia*, 3 an increase of the diffusible alkali and a concomitant diminution of the total alkali (Frisch and Walter), and 4 a "dysregulation" of the NH_3 concentration However, the undisturbed regulatory mechanism of the epileptic prevents any actual change in the blood's reaction The increased convulsive tendency brought about by hyper-ventilation is not accompanied by an actual change of the circulating-blood to an alkaline reaction

Serial basal metabolism determinations reveal a unique, marked variability in the amounts of oxygen consumed The variations may reach an amplitude of 40 per cent. The values of the specific dynamic action of protein also show similar but less marked fluctuations In 60 per cent of the cases, the reaction of the protein addition remains under normal The nutritional investigations of Kauffmann and deCrinis show a preparoxysmal lessening of oxygen consumption and carbon dioxide production but without parallel curves Carbohydrates, proteins and fats are all involved Consequently variations in the respiratory quotient occur revealing incomplete oxidation The variations are believed to be due to disturbances in the activation of the inactive circulating hormones This is the result of changes in the peripheral autonomic cellular metabolisms and varying impulses emanating from the central nervous system control It is significant that acidotic animals show a diminution of oxidative processes (Chvostek)

The serum protein colloid picture of the epileptic shows a characteristic deviation toward phases of high dispersion, which is especially manifest preparoxysmally and during a series of attacks The amount of the total blood protein is raised, such increase is taken up entirely by the albumin quota Remarkable variations are encountered here also The coarse dispersion fraction gives normal values This deviation to higher dispersion conditions the increased water retention and is associated with the increased calcium content of the blood The typical blood changes are to be regarded as the "humoral mirror picture" of the tissue changes

The lessened nitrogen excretion in the preparoxysmal phase is interpreted as the consequence of the inhibited protein splitting and synthesis at this critical time so that actual nitrogenous intermediate products circulate about which have no physiological but rather a toxic action

The extraordinary significance of these complex colloidal changes is shown by the fact that drugs producing deviation to the right (high dispersion) excite convulsions and those that provide a left deviation (coarse dispersion) inhibit seizures

The residual nitrogen and blood sugar fluctuate but are elevated preparoxysmally The blood cholesterin is also elevated at this time.

Electrolytic changes, colloidal reactions, hormonal influences, vegetative nervous impulses play in concert upon the cell's surface (colloidal "membrane") and interior, altering the permeability of the former and the irritability of the entire unit Hober illustrates these complex interrelationships in the treatment of epilepsy as follows 1 sedative therapy erects a narcotic barrier between the cell and its milieu 2 Withdrawal of NaCl and calcium administration dehydrate the colloidal "membrane" and produce a "condensation barrier" 3 The attack itself "unloosens" the cell so completely that its responsivity to stimuli is much reduced for a considerable period

In Table II, I have attempted to show the interrelationship of these important changes The peculiar heightened dispersion of the colloidal protein produces retention of water and increase of calcium The lessened oxidation permits the appearance of acids (which disrupt the acid—base equilibrium) and causes an increase of the residual nitrogen The latter may also be, and the increased blood sugar and cholesterin are, attributable to sympathetic hormonal dominance

As a result of their studies, Kraus and Frisch emphasize the disturbances in the physicochemical life of the body cells and fluids as the essential disturbance in epilepsy The remarkable fluctuations present in all the individual physicochemical processes again reflect the unstable cell-blood exchange A hereditary constitutional defect (comparable to that seen in diabetes mellitus) must underlie this remarkable disease

TABLE II

Physico-chemical Changes in the Preparoxysmal Period of Epilepsy

1 Retention of water and sodium chloride.
2 Increase of blood calcium (from subnormal)
3 Deviation to high dispersion of blood colloidal protein (albumin), so-called deviation to the right.
4 Acidosis—a Lessened alkali reserve (hypocapnia),
b Reduced CO_2 combining power,
c. Diminution of total alkali with increase of diffusible alkali
5 Lessened oxygen consumption and carbon dioxide production. Falling of the respiratory quotient
6 Increase of residual nitrogen in blood
7 Increase of blood sugar
8 Increase of blood cholesterin
9 Increase of electrical excitability of peripheral nerves

Dominance of sympathetic (adrenal) hormonal influences

THE CEREBRAL FACTOR

The cerebral factors may now be considered. They are enumerated in the following table

TABLE III

Cerebral Factors

A—Diseases

1 Neoplasms (including bony growths)
2 *Congenital and heredo-degenerative disease*
3 Degenerations and scleroses (viz., multiple sclerosis, tuberous sclerosis, encephalitis periaxialis diffusa, senile cortical atrophy, presenile gliosis, etc.)
4 Traumatic processes
5 Infections and parasitic disease (viz, lues, tuberculosis, encephalitis, abscess)
6 Vascular disease (vascular spasm, arterio-sclerosis, hemorrhage, emboli)

B—Irritants

1 Mechanical (viz, air)
2 Electrical
3 Thermal
4 Chemical (viz, strychnine painted on the cortex)

C—Psychogenic Processes

1. Theory of Regression (L. Pierce Clark)
2 Theory of Rosett The normal epileptoid reaction.
3 Hysteria

From the above table, it becomes evident that almost all organic cerebral diseases can induce the convulsive state Is it possible to find a single pathological determinant common to all which is the true cerebral factor?

MacRobert, in this country and Muskens abroad, both suggest dysmyelinization as a possible factor The former stresses "anatomic defectiveness in which the vital feature is a paucity of functionally active fibre tracts This specific defect may be but a part of a wide spread neural agenesis or may exist alone, the result of a failure in the final stages of development, namely, myelinization of the nerve fibres" A kind of defective insulation of the nervous stimulus results *In this* connection, paroxysmal spasms are rarely encountered in amaurotic familial idiocy, although Hassin stresses the frequent occurrence of decerebrate extensor hypertonus B Sachs does not regard convulsions as an essential part of this disease in *which almost all the ganglion cells of the* nervous system degenerate Whereas in encep-

halitis periaxialis diffusa of Schilder, a disease in which the fibre tracts suffer most in a dysmyelinization process, convulsions are frequent Yet the dysmelinization theory hardly seems tenable when one considers the important humoral factors It has not been proven by any of the finer anatomical studies, and throws no light on the convulsive state produced by certain vascular conditions to be described

The observations of O Foerster seem to show that in the vascular mechanism of the brain we will find the *basic cerebral factor* On the operating table he has observed at least one hundred times a preparoxysmal vaso-constriction and anemia of the exposed brain with a diminished volume The tonic convulsion then occurs with a rapid fall of cerebrospinal fluid pressure. The removal of cortical function due to the vasoconstriction permits the unbridled or isolated centers in the brain stem to manifest this tonic decerebrate phase, and serves to explain the unconsciousness Then venous stasis comes on rapidly, accompanied by a great increase in brain volume and cerebrospinal fluid pressure The stasis now produces cortical irritation and the clonic (Jacksonian) phase appears This vasomotor theory (Nothnagel explains the attack's sudden onset and cessation, and the radiation of a Jacksonian cortical attack The sensory aura and the postparoxysmal weakness may be ascribed to transient loss of function from local anemia Further weight is lent this vascular basis when we consider the various vascular conditions which are able to provoke the convulsive state

TABLE IV

Vascular States

A—Disease of Cerebral Blood Vessels

1 Arterio-sclerosis
2. Endarteritis obliterans
3 Angiospastic migraine.
4 Raynaud's Disease
5 Aneurysms
6 Embolism.
7 Congenital smallness of carotids or vessels of the Circle of Willis

B—Changes in Cerebral Circulation

1 Heart Block.
2. Restoration of previously impaired cerebral circulation.
   a. After drowning,
   b After strangulation,
   c. After suffocation.
3 Pressure upon, or ligation of carotids and vertebral arteries

Recently more evidence favoring the vasomotor theory was given by the work of O B Meyer Pieces of cortical arteries show rhythmic spontaneous contractions when placed in normal serum These can be kymographically reproduced It the serum of an epileptic be used the contractions are absent or diminished, this occurred in 15 out of 17 cases irrespective of the time (with regard to the paroxysm) of the withdrawal of the serum In six cases of hyperthyroidism the contractions were increased

Some years ago, Mac Robert and Feimer explained the frequency of the convulsive state in temporal lobe neoplasms by assuming that the pressure of the tumor interfered with the circulation in the overlying Sylvian artery

Increased cerebrospinal fluid pressure of itself does not cause convulsions (W M Kraus), but if other factors are present then such increase will help precipitate the convulsive state (Elsberg and Pike)

The convulsive state has also been regarded as essentially of psychogenic origin, especially by L Pierce Clark Following the psychoanalytic approach, he regards the fit as a regression, a withdrawal from reality into the blessed Nirvana of the intrauterine foetal state Objections to this point of view are many It does not account for the occurrence of convulsions in deep sleep (which, in itself, is an adequate escape from reality), the incidence of convulsions in animals of the mammalian phylum, nor does it explain the status type of convulsion with its frequent fatality This point of view in no way clarifies the convulsive state based on known organic conditions as general paresis, tumor, etc.

In a somewhat different category is the ingenious theory of Rosett. He believes that normally, "a stimulus requiring sudden movement on the part of the organism or the narrow focusing of attention, and certain functions such as sleep, defecation, sneezing, coughing, parturition, lead to a temporary reduction or extinction of the cerebral functions" This may lead to a "tonic contraction of the entire skeletal musculature resulting in the posture of decerebrate rigidity"

"The biologic purpose of the reaction is the automatic fixation of the relatively central joints preparatory to any possible needed movement of relatively distal segments of the body and limbs" To its normal incidence he applies the term "normal epileptoid reaction"

Perhaps this conception helps to explain the tendency of the seizures to appear as the individual is going to sleep or awakening ("Vorzugsmomente" of the German writers), and the very occasional appearance of convulsions in the beginning of ether or chloroform narcosis (Patch)

Yet Rosett is not able to explain the reason for the appearance of that periodic, massive, exaggerated response which constitutes the convulsive state. He has contributed some interesting psychological side lights to the problem

To discuss the hysterical convulsion would require a consideration of hysteria which would take us too far afield Obviously, its mechanism though related to, is different from, the convulsive state herein considered

Heredity

Many have emphasized the element of heredity in the convulsive state. In his recent analysis, Muskens shows that about one-third of his cases

had epileptic forbears in the direct and collateral line About one-eighth revealed insanity in the direct and collateral line In heredity, alcohol played a part in about one-twentieth of the cases, and lues in only about one-fiftieth Striking as these figures are they do not aid us at all in the study of the fundamental causes of the seizures

"Reflex" Epilepsy

Before speaking of the pathology, brief reference may be had to the so-called "reflex epilepsy" which belongs in the field of romance Diseases in the nasal, aural, dental, genital and other spheres were held responsible for the attacks in some mysterious manner In his analysis of two thousand cases, Muskens found no instance of this type Today we hear very little of this old myth

Pathology

Is there a fundamental pathology to the convulsive state? To be sure, ganglion cell degeneration, subpial marginal gliosis, and other more generalized glioses have been described Gerstmann found atypical and even foetal cells in the molecular cortical layers Volland found regulary karyolytic and degenerative changes in the anterior horn cells in myoclonic epilepsy A milky cloudy pia has been the sole finding in cases of focal epilepsy in which biopsies have been obtained (Muskens, et al) Alzheimer at one time (1898) even went so far as to say that ("Man könnte die epileptischen Anfälle als Folge eines Druckes ansehen, den die herbere geschrumpfte Rindenoberfläche auf das tiefer liegende Hirngewebe ausübe ") one could regard the epileptic seizure as the result of pressure, which the sharply shrunken cortical surface exerts upon the deeper cerebral parenchyma Yet with the passing of time, a different attitude of mind has been forced upon most observers This is due to the fact that negative findings have been recorded by careful observers in cases which had neither lasted too long nor been accompanied by mental deficiency or dementia The general opinion now held is that the pathological changes found are the *result* of the long enduring process, not the *cause* (Binswanger, Zabriskie, et al) Hence the idiopathic convulsive state has no essential cerebral pathology Alzheimer and his pupils believe that the convulsive state is a common attribute of warm-blooded animals, and is to be regarded as a reaction produced by a humoral poison on a nervous system in which lessened tolerance, or lowered threshold, has been brought about

All the facts fit in with the above conception It permits the study of neural and extraneural factors, the cerebral and the *important humoral ones* It would seem, then, that the convulsive state is either brought about by (1) a group of poisons operating upon the cerebral vascular mechanism producing vasoconstriction and cerebral anemia, then congestion, (2) by local cerebral disease or disturbed vascular conditions upsetting the vascular equilibrium or (3) by combinations of the above[2]

Therapy

The therapy of so-called idiopathic epilepsy may be considered under certain headings (following Muskens)

1 Hygienic and fit—prophylactic measures
2 The treatment of
  (a) The established case,
  (b) The stubborn case,
  (c) Status Epilepticus
3 Surgical treatment of traumatic epilepsy

I Hygienic measures and the prevention of the seizure

In cases where one or a few minor or major seizures have occurred or where heredity or suspicious prodromata (known to have preceded an attack) make one suspicious of the development of this disease, one may restrict the treatment to certain dietetic and other measures without using sedative medicines These prodromata may consist of one or more of the following—constipation, coated tongue, malaise, especially *myoclonic twitches,* mood changes, irritability, headache, hyperidrosis, gastric or other abdominal distress The patient and those taking care of him should understand explicitly and follow slavishly the following admonitions A careful record should be kept of all unusual symptoms for the physician's guidance Constipation is to be avoided A glass of warm water should be taken night and morning Abdominal masage with a wooden ball, cereals, such as bran with *stewed* fruit, night and morning and mineral oil at night are useful. If no movement has occurred by mid-day, a soap enema should be given, colonic irrigation two or three times a week may remove toxic material and promote large intestine activity In stubborn cases, the addition to the mineral oil of agar-agar and phenolphthalein (as in a number of proprietary mixtures) may be of aid Gastro-intestinal X-ray studies should be made more frequently A ptosed stomach, a redundant or spastic colon, adhesions, etc , are brought to light not infrequently, and require special treatment. Examination of the feces is in order Intestinal worms require vermifuges

In general, fasting should be avoided Muskens advises that a piece of zwieback be eaten quite soon after awakening Alcohol and coffee should be strictly forbidden (caffeine-free coffee can be used) *Raw* fruit, fresh bread, rich salads, chocolate candy, fancy desserts and overeating ought to be avoided The patient should eat simple

[2] Despite the emphasis now laid on the humoral factors, it must be evident that the cerebral lesions not only determine the type of symptoms produced but also undermine the natural resistance of the nervous system against convulsive seizures. Such lesions then, as loci minores resistentiae, form part of the vicious cycle.

foods often and a little at a time, rather than heavy meals at set intervals Careful chewing is necessary, to promote which all bad teeth require fixing One hour's midday rest in bed following luncheon is an essential An ambitious school child may have to be put on a partial school day Specific allergic food poisoning may be suspected and skin tests employed

The high fat or ketogenic diet has been recommended by Peterman, Talbot and others in children Convulsive seizures are said to disappear completely in one-third of all children so treated Adults react less advantageously Normally the fat carbohydrate protein ratio is as 1 4 In this high fat diet the attempt is made to reverse the proportions 4 1 The fat is gradually increased in order not to upset digestion The minimal protein requirement during this dietary regime consists of about 1¼ grams of protein per kilo (Talbot) Acidosis, ketosis, lowering of the blood sugar and diminution of the blood's alkaline reserve result The ketosis causes an increase of calcium excretion without altering the blood figures at any time Hence, the giving of calcium lactate (2 to 3 grams daily) (Talbot), is advised to prevent decalcification The acidosis alone or the ketosis alone do not control the seizures One may give enough sodium bicarbonate to render the urine alkaline without causing an attack (conversely acidosis attained by the administration of large amounts of ammonium chloride does not control the seizures) While it would seem that the ketosis produced is the more important factor in preventing the seizures, further work is necessary to settle the problem

Overstudy, too little sleep, religious controversies and other arguments, "thrilling movies," "heavy" reading before bed, gambling or excited card play and sexual excesses are forbidden Smoking should be cut down, nicotin free cigarettes should be used by preference Head injury, even trivial "bunking" is to be avoided, likewise inversion of the head (as in digging) or too much exposure to sun.

The physician should carefully investigate the circumstances preceding the *first* seizure and attempt to remove the particular provocation In this connection, the value of a keen nurse, or observing relative, cannot be overestimated I have laid particular stress on this phase of the treatment because we can prevent the seizures in a number of patients by scrupulous attention to the aforementioned details Unfortunately the neurologist or other physician sees the patient when the attacks have set in with such regularity that sedative medication is needed in addition

The Treatment of the Established Case

All hygienic details are to be enforced

Luminal has proven of considerable value and has supplanted the bromides Elixer of luminal should not be used in this connection because of its alcohol content A tablet of ¼ to ½ gr is given three or four times a day If there is a tendency to seizures during the night, one-half to one and a half grains may be given on retiring and less during the waking period (one-half to three-fourths of a grain) For those whose seizures appear very soon after arising, the dosage may be "massed" at that time instead of on retiring

The bromides are usually given in equal parts of the potassium and sodium salt If the amount of NaCl eaten is curtailed it should not be necessary to go beyond 60 to 70 grains a day in early cases In older recalcitrant types higher dosage may be needed To offset the tendency to skin erruption, Gower's suggestion, viz, the concurrent use of Fowler's solution is helpful To prevent arsenic accumulation, it is advisable to stop this adjuvant from time to time, viz, one week out of three

Recently Notkin (The Regulation of Chloride-Bromide Intake in Epilepsy—The Psychiatric Quarterly, October, 1927), reported better results with a balanced bromide—chloride therapy, than with luminal He used a proprietary drug, "Sedabrol," which is a small bouillon cube containing about 1 1 grams of sodium bromide and 0 1 grams of sodium chloride. Two to six cubes a day were given, at times luminal was added Except for the elimination of salty foods, the usual amount of table salt was allowed The basic idea of this therapy is an old one It is to have a balanced proportion between the amount of bromide substituting the sodium chloride in the body, and the retained sodium chloride, with the avoidance of bromism However, I fail to see why a proprietary drug must be used to accomplish this object.

Incidentally, the ease with which the chloride and bromide radicals replace each other in the body provides an almost specific treatment of bromidism, viz, sodium chloride internally, and externally (in the form of sodium chloride solution compresses) if the bromide skin eruption is troublesome Rather than ascend to the higher doses of bromide, many combine luminal and bromide especially when the efficacy of one or the other drug has waned Borax has also been used especially abroad, in doses of one to three grams per day, usually with bromides I have used sodium biborate in doses of grains V to XV, three times a day alone, and with luminal and bromide especially when treating persistent petit mal seizures The addition of calcium lactate to one or combinations of the foregoing drugs in doses of grs V to X, three times a day, is of occasional value

For petit mal, Gowers advised nitroglycerin, two to five or more drops of the 1 per cent solution It may be used with the bromides, and is said to be effective in those cases with a poor peripheral circulation, cold fingers, etc. The stability of the nitroglycerin solution may be enhanced by the addition of a few drops of dilute

hydrobromic acid (Muskens) As a reserve of "extra medicine" to anticipate a known exciting factor, Muskens advises the following mixture, the parts being—tincture cannabis indica, five to ten, potassium bromide, twenty-five, gum arabic, q s , aqua, 1000, in doses of one to four spoonfuls a day This combination is also of value in the treatment of the prodrobromata, or as an added medicine to be taken a few days before (two spoonfuls), during (three to four spoonfuls), after (two spoonfuls), the menstrual period It should not be suddenly stopped but gradually reduced

The indiscriminate use of the endocrines is to be deprecated If there are signs of pituitary disease (viz , large upper spaced central incisors, acromegalic or hypopituitary (Froehlich) features *x*-ray evidence of small or malformed sella turcica), whole pituitary gland may be used in doses of gr ½ to iss three times a day In mild cases, pituitary gland may be tried alone, usually one of the aforedescribed sedatives is also added In certain women, the attacks are apt to occur only directly before, during or just after the menstrual period or are much worse at that time In these cases, I have increased the amount to one and a half or twice the sedative medication, during the six or seven days involved and have given whole ovarian substance gr I to III, three times daily continuously, over a longer period of time Occasionally, thyroid gland may be added either to the pituitary or the ovarian gland Of course as the seizures lessen, the sedative drug should be reduced in amount but the patient, the nurse or the relatives should be carefully instructed *not* to stop any of the medicines because they "ran out of it and were going to see the doctor in a few days anyway" A number of attacks, even a status epilepticus may be so induced in a case which has been running a favorable course Such reductions should be carried out under the physician's continuous surveillance

For the stubborn case which has not responded to the foregoing, Muskens uses the "Iodide- mercury course" Other medications are stopped, the patient is put on a pill of iodide of mercury 050 gm (a high dosage), one to three times a day for about fourteen days, or until gingivitis or diarrhoea or vomiting or fever or backache appear The dose is lessened but the medicine is kept up until the above symptoms show that further treatment is inadvisable While the patient is taking this treatment and for a time after it, Muskens uses a bread-loaf in which has been incorporated, zinc lactate 120, zinc oxide, 100 grams, borax 1 gram and bromide 5 grams The patient eats this bread vehicle with its contained medication in the same way as he eats ordinary bread I am not aware of its use in this country Some very laudable results are said to have followed the above program in the recalcitrant cases

Special colonization of the deteriorated or hopeless epileptic and institutionalization of the insane or criminal type offers no special problem at this time

Status epilepticus—This justly feared manifestation can be sometimes prevented if dietetic errors, omission of medicine or other gross neglect of the rules of treatment can be obviated When present, chloroform or ether inhalations, high enemata and a quiet darkened room are the first requisites Then luminal-sodium or paraldehyde intravenously, or the bromide chloral mixture rectally are employed Intravenous strophanthin or digalen may be needed to combat a failing heart

Surgical treatment of traumatic epilepsy Although surgical procedures are of very doubtful value in the idiopathic types of this disease, they have a distinct field of usefulness in traumatic epilepsy Splinters of bone subdurally located, adherent dura with enlarged veins, serous encephalitis, localized brain swelling, foreign bodies in the brain substance, pia-arachnoidal cysts, meningeal adhesions, etc, have been successfully treated in a number of instances However, no operation should be considered before the hygienic and medicinal treatments above outlined have been given a thorough trial

The relation of the trauma to the convulsions must be definite In this connection, it should be noted that four or five years may elapse between the time of injury and the onset of the convulsions Headache may occur during the interim The long duration of the seizures even if generalized is not a contraindication to operative intervention A scar with an underlying bony depression or defect is very often present Focal organic signs or Jacksonian seizures should occur Local or generalized headaches may be present Where the Jacksonian twitches persistently lead to generalized convulsions, European surgeons, following Sir Victor Horsley, operate and remove the offending cortical center, which must be carefully delimited by electrical stimulation The resultant paralysis (monoplegia) is a price worth paying, for the elimination of the distressing generalized attack Careful postoperative treatment is necessary similar to that employed (as above) in the prevention (hygiene) of the non-traumatic convulsions

SPONTANEOUS RUPTURE OF THE HEART CASE REPORT*

By MAURICE PACKARD, M.D., and H. F. WECHSLER, M.D., NEW YORK CITY

Due to its dramatic nature, medical literature contains a superabundance of case reports of this condition, spontaneous rupture of the heart. However, as Krumbhaar and Crowell point out in their exhaustive review of the subject, a great many of these are so woefully deficient in important details, that the completeness of both the clinical and pathological observations has led us to publish the following case.

G. B., white male, 55 years of age, born in Russia, was admitted October 24th, 1927, with the history that three days previously, after a heavy meal, he was suddenly seized with severe pains high up in the epigastrium. He perspired copiously and had an intense fear of impending death. The following night, the pains recurred, and were more severe and viselike in character. They were now situated in the left epigastrium and radiated to the umbilicus. This attack had persisted until the present, the pain finally localizing to the region behind the lower end of the sternum. The day before admission he had twice vomited with temporary relief of his distress.

His past history was negative except for mild dyspnoea on exertion, severe heart-burns and eructations for the past month. For years he had smoked 60 cigarettes a day.

His physical examination revealed drowsiness and pin-point pupils due to the morphine administered, markedly labored respirations which later became Cheyne-Stokes in character, and moist rales at the base of both lungs. The heart was moderately enlarged to the left by percussion. The apex beat could neither be seen nor felt and the heart sounds were barely audible. No murmurs were heard. The pulse was 110, soft and regular. His blood pressure was 90/80. The abdomen was distended and there was slight tenderness in the right upper quadrant and in the epigastrium. The temperature was 99° F.

Laboratory findings were: Hgn. 85 per cent., R. B. C. 4,250,000, W. B. C. 23,800, polys. 85 per cent., lymph. 8 per cent., tr. 7 per cent., urine, albumen 2 plus, microscopic negative.

The evening of his admission, he suddenly became convulsed and markedly cyanotic, foamed at the mouth and vomited about two quarts of watery fluid. His pupils became widely dilated. In the space of two minutes, his heart and respirations ceased. The peculiar rushing and roaring sound heard over the precordium, which has been described in a single case, was not audible.

Autopsy. The pericardium was distended with about 350 c.c. of fluid and clotted blood. The heart was enlarged, weighing 450 gms. and measuring 11 cm. by 10 cm. by 6 cm. Situated in the upper third of the anterior surface of the left ventricle, 7 cm. above the apex and 3.5 cm. to the left of the septum, was a ragged, linear rupture of the epicardium, myocadium and endocardium (Fig. 1). Externally, the tear measured 1.6 cm. in length and ran roughly parallel to the septum. Its endocardial opening was practically of equal length and situated about 2 cm. posterior to the papillary muscle of the aortic cusp of the mitral valve. The left ventricle was concentrically contracted and markedly hypertrophied, its wall measuring 2 cm. in thickness, except in the neighborhood of the rupture, where for a radius of 1.8 cm. the wall became abruptly thinner. At the actual site of rupture, the wall measured only 0.4 cm. The muscle here had a mottled, brownish-red appearance interspersed with brighter red areas and irregular blackish streaks. The myocardium elsewhere was dull brown in color. The right ventricle was dilated and measured 0.4 cm. in thickness. Except for slight thickening of the free edge of the mitral and aortic cusps, the valves were negative.

FIG. 1

Spontaneous Rupture of Heart. Stylet in Rupture.

The aorta showed a moderate atherosclerosis. Both coronary arteries were tortuous and markedly calcified. Situated in the descending branch of the left coronary artery, 1.5 cm. from its origin, was an adherent thrombus which occluded the lumen of the vessel.

Anatomical Diagnosis. — Atherosclerosis of

PERSONAL EXPERIENCE WITH UTERINE PROLAPSE*

By GEORGE B BROAD, M D, SYRACUSE, N Y

MY PAPER is largely a review of my recent work with uterine prolapse. No attempt will be made to discuss at length factors involved in the causation of this affliction. It is pretty well understood fascia enters very largely in supporting tissues of the body The pelvis is no exception Surgical procedures based upon this principle bid fair if they are properly chosen, to meet with the greatest number of successes in dealing with mechanical defects The trauma of childbearing at times attenuates and undermines the strength of the fascial plane of the pelvis, especially the fascia under the bladder and more particularly that extension of this fascia going back to the uterus, known as theuterovescial fascia Could this fascia be preserved, we would see but little uterine descensus I do not underestimate the fascia of the pelvic floor This is essential but it plays a role secondary in importance to the fascia of the anterior vaginal wall The condition of the cardinal ligaments of the uterus has to be considered in discussing the factors leading to uterine descensus The number of children borne play a very minor part in the causation of uterine prolapse We have all seen the exceptional instance of uterine prolapse in the young unmarried woman, who has borne no children. The relationship of cervical elongation to true uterine descent will not be discussed although it is invited at this point

A discussion of the numerous plans for replacing prolapsed pelvic organs in a very natural way falls into two groups first, utilization of the fascial planes by vaginal operations, restoring these structures by one of several procedures such as the Ward, Fothergill or allied operations Secondly, the combined operation of suspension of the uterus or even its removal, together with plastic work, such as the Gillium with its many modifications or even hysterectomy with implantation of stump We may add to these two main groups certain special operations where a different principle is involved, like the Mayo vaginal hysterectomy which uses the broad ligaments for part of the bladder and anterior vaginal wall support, also the Watkins Wertheim interposition operation I would like to say at this point that every one of these procedures has its place in overcoming the descent of pelvic organs My paper deals largely with the interposition operation because in my hands it has most satisfactorily accomplished the results, if at all indicated The indications for this operation have enlarged with my experience Most operators have accepted the indications for this procedure about as follows Uterus in moderate prolapse, say the first or second degree, an organ not too large in a patient past the childbearing period. I agree most decidedly with these indications In my work, I have made the limits a bit wider I use this operation in a selected few in the childbearing period who give their consent, if they have already had children and are physically unfit to bear more I usually in the childbearing period limit the application of this operation to those in the very late 30s or early 40s Of course, the patient must be sterilized This is usually done by removing the tubes and resecting a portion of the uterus where the tube is attached I have also adapted the Watkins interposition idea to uteri that under ordinary conditions would be too large for the space If I feel the size is a definite hindrance, I resect a portion of the uterus, leaving enough of the uterine body when sutured together to adequately support the bladder, not following the Bissell plan of removing most of the uterine musculature

I have repeatedly found it necessary to remove minor pathology, the most frequent, of course, being small uterine fibroids I have on a few occasions been forced to change my plan. Where an interposition operation was intended, if I do not think the structures adapted to this procedure, I have changed the operation, doing a Mayo vaginal hysterectomy I have to confess I do not think I do as satisfactory a Mayo operation as is done by many experienced operators To me it is rather simple to remove the uterus by this method but it is not so easy to feel that I have secured the upper vaginal vault At times I have a sense of insecurity concerning the adaptability of the broad ligament to support the bladder unless a rather complete radical cystocele operation is performed I find in the Mayo operation, I am inclined to narrow the upper vagina more than I should I believe I can utilize the uterosacral ligament as an anchor for the upper vagina more than I have in the past.

I have had no experience with the Baldwin-Emmett or similar operations

In patients in the childbearing period, where this function should be preserved, I practically always do a combined operation, namely, combined plastic with suspension, generally the Simpson modification of the Gillium or the Oldhausen I rarely remove the uterus from above, trusting to any operation utilizing the cervical stump It has fallen to my lot to re-operate an occasional patient for prolapse where the operator attempted to correct uterine prolapse by an abdominal supracervical hysterectomy and failed. Secondary operations where uterus has been removed, I consider among the most difficult Under such conditions, I suture the freshened cervical stump to the abdominal wall by non-absorbable sutures I have found the technique in this operation somewhat simplified if the cervical

aorta Coronary sclerosis Thrombosis of left coronary artery Infarction of myocardium of anterior wall of left ventricle with rupture through the infarct Hemopericardium Hypertrophy of left and dilatation of right ventricle

Histology—The myocardium about the rupture was the seat of an hermorrhagic infarct (Fig 2) The muscle fibres here had completely lost their nuclei, were swollen and their striae indefinite Marked hemorrhage was present between the fibres and there was an infiltration of polymorphonuclear leucocytes and microphages Many of the latter contained pigment. About the periphery of the infarct were found marked hyperemia and fatty degeneration of the muscle fibres Sections through the left ventricle near the apex showed a marked interstitial fibrosis The left coronary artery exhibited marked atherosclerosis

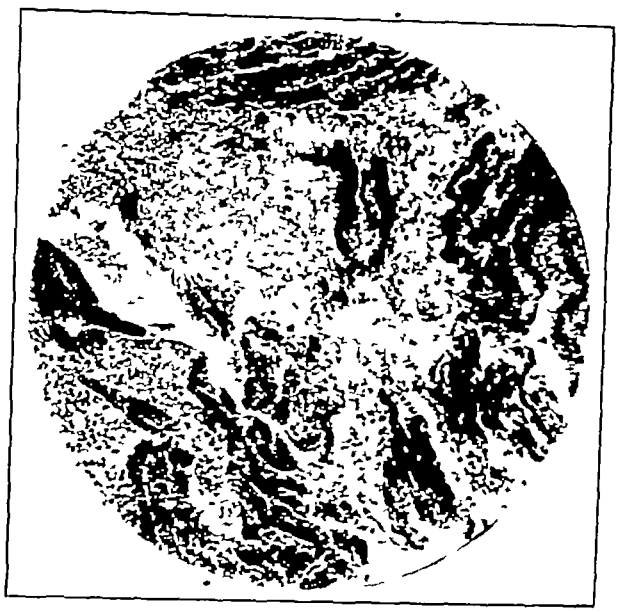

FIG 2
Hemorrhagic Infarct, left ventricle

and a partially organized thrombus in the lumen of the vessel (Fig 3)

Histologic Diagnosis — Coronary sclerosis with partially organized thrombus Hemorrhagic infarction of myocardium Myocardial degeneration and fibrosis

Comment—The case here reported is an exceedingly typical one of spontaneous rupture of the heart due to coronary disease It closely parallels the most frequent clinical and pathological findings in this group which comprises the vast majority of the 654 cases studied by Krumbhaar and Crowell The only deviation is the age of our patient which is somewhat below the usual age in which this condition occurs

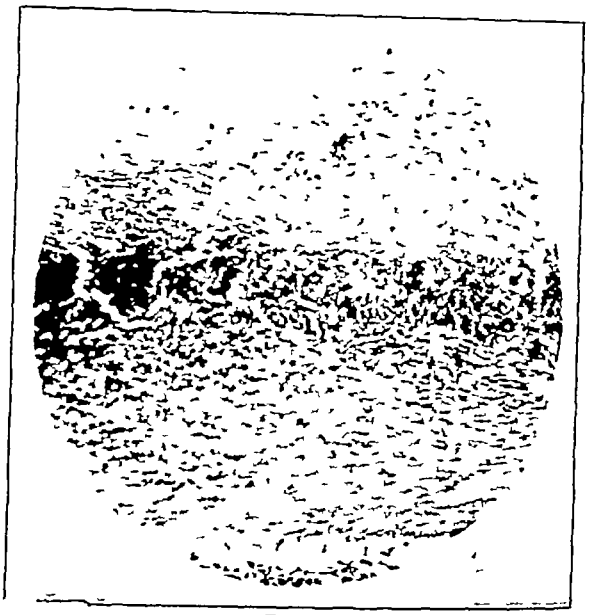

FIG. 3
Organizing Thrombus in Left Coronary Artery

Among the interesting features are the huge number of cigarettes consumed by the patient and its possible relationship to the coronary sclerosis, the diagnosis of coronary thrombosis, and then the actual observation of the patient at the time of rupture while he was lying quietly in bed That an increased intracardiac pressure is not the exciting cause of the rupture in our case is shown by the blood pressure Apparently the cause must be sought in the site, the character, and the rate of necrosis of the infarct

FIG. 3 X 250 Organizing Thrombus in Left Coronary Artery

I have combined under abdominal operations the vaginal suspensions, chiefly the Simpson modification of Gillium and Oldhausen, always with plastic work, also one case of complete prolapse of cervix and bladder, original hysterectomy having been done elsewhere. In this case the stump was sutured to the abdominal wall, followed by vaginal plastic work In dividing the results into symptomatic and anatomical groups, the number of cases is again not great enough to be conclusive but is indicative Thirty-two out of thirty-eight cases submitting to interposition operations were cured of all symptoms Four had definite urinary symptoms One of the cases with urinary disturbances had a feeling of desiring to empty the bladder frequently Another patient had a feeling that the bladder was incompletely emptied although in neither of these cases were the symptoms particularly annoying There were two cases of urinary incontinence. This incontinence occurred before the operation In both of these I did a Kelly sphincter constricting operation in addition to the interposition In both cases patients were improved but not entirely cured I believe these two cases should not properly be charged against the interposition operation. Another one of my patients was conscious of some bearing down in the pelvis when on feet for a long time She is one of the two cases with anatomical defects In another the cervical stump was pointing partway down vagina when patient strained No symptoms There was one failure. I did not see this patient but her physician said she could force cervix down so it appeared at the vulval aperture She is now practically an invalid from other causes and he reports but little inconvenience from her descensus

In the eight abdominal cases, all were symptom-free The vaginal hysterectomies were comfortable. Two patients upon whom the LaForte operation was performed are symptom-free for descensus, although in one case I have been forced to divide the bridge holding the organ back because of uterine bleeding, which reappeared nearly sixteen years after menopause, exciting suspicion of cancer of the uterus I regret to say we found a cancer in the body of the uterus in this patient

I have found it almost impossible to be accurate in my anatomical tables I have used the term "satisfactory" to signify the result in this table Many of the anatomical results seem perfect if that term can be rightfully used in any operation of this kind. In many others, there was a slight prominence in the anterior wall where uterus was sutured in the interposition operation Minor defects I have not recorded but have reported them in Table No 3, as comprising practically 20% of cases inspected They were inconsequential and patients were unconscious of their presence I have recorded only the gross defects In one there was a definite sagging of the anterior vaginal wall of which the patient was conscious In the second there was a definite descent of the cervix in upper vagina, causing no symptoms This was the patient referred to in Table No 2 There was one complete failure There were no gross defects in the abdominal group In the vaginal hysterectomies one of the patients has a narrowing of the vagina in the upper part, producing no symptoms at present

In one of the LaForte operations, the uterus had descended down the gutter on one side but was producing no symptoms The one death reported in Table No 1 was caused by an infection This patient was a fairly good risk although uterus was large It was one of the cases in which

stump is grasped on the vaginal side by a tenaculum left in the vagina When the abdomen is opened an assistant by pressing the vaginal tenaculum forward and upward at once locates the cervical stump from the abdominal side, very much simplifying one step in the procedure

There is one operation for uterine prolapse that is nearly obsolete I have never seen it done by another and surely the occasion for its use must be infrequent Yet there is an occasional aged widow whose general condition is such that any operation requiring a general anesthetic would be hazardous I have on three occasions under the above conditions performed the LaForte operation which consists of denuding a central pathway through the anterior and posterior vaginal walls from the vaginal introitus to within 1½ inches of the cervix This denuded area can be as wide as one wishes and can be made under local anesthesia The suturing together of this denuded pathway, when healed, forms a bridge down the center of the vagina, which supports the descending organs Enough mucosa is left on either side to permit the escape of cervical discharges

I presume every operator develops points in his technique which may not have been described by the original operator but are used by him to obtain results These can hardly be called modifications of the operation although they may explain his success in part in any particular operation I was once told by an observer that I did more than the usual Watkins interposition I was told I utilized the uterovesical fascia in obtaining a strong fascial plane in closing the anterior vaginal wall over the cervix Of course, I do this intentionally, for it holds the cervix more strongly in place in the upper anterior vaginal wall

I also wish to emphasize the fact that I amputate practically the entire cervix in every interposition operation A secure operation on the posterior vaginal wall is to my mind very important The operation as performed by the late and revered John G Clark is the one I prefer to do It makes a rectocele or an enterocele practically impossible It considers the posterior wall as a true hernia as it properly should and makes secure the fascia plane over the rectum well up to the cervix

When I have finished the interposition operation, I like to think of the uterus as a living pessary, holding the bladder securely upward, anchored in place by strong fascial planes, the initial sutures securing the uterus to the fascia near the pubes anteriorly, one central suture always extending from the uterine fundus to a point near the vesical sphincter

The tabulation of results in a condition like uterine prolapse is open to many errors It is rather difficult to draw conclusions from it in a comparative way For instance, the degree of prolapse If the three-degree division is attempted, the first and second degrees may blend so closely that borderline cases might easily be placed in either group The personal equation cannot be disregarded There can be no difficulty whatever in tabulating third degree or complete prolapse cases if the uterus is entirely outside of the vagina but if it is only partly outside, again error creeps in To simplify classification, I have grouped all cases with uterine descensus to the vulval aperature in one group, and all cases where a major portion of the uterus is outside in the second group This classification answers my needs for the present paper Another difficulty is encountered in tabulating results Perfect anatomical results with cure of all symptoms is the ideal There may be minor anatomical defects of which the patient is unconscious, without symptoms I have divided operative results into two groups The first table having to do entirely with symptoms and the second table having to do with the anatomical results I have attempted a tabulation of 100 cases of uterine prolapse operated by me These cases largely represent my experience with this affliction during the past five and one-half years, but not entirely I have taken these cases from the records of only one hospital where I do most of my work They have been chosen consecutively without any attempt at selection I have added two cases outside of this group in order to present to you the LaForte operation These two patients were operated upon by me about ten years ago

Chart No 1 shows the sub-division made in selection of operative procedures The Watkins interposition operation was performed in fifty-five cases The abdominal operation which combined suspension and fixation with plastic work, 30 cases Vaginal work alone which includes the vaginal hysterectomies with the LaForte operation, 15 cases The mortality was 1 When degree of prolapse was considered, an attempt was made to divide this list into the two groups above mentioned I felt we could place approximately fifty-five cases in the first group, namely, first and second degree prolapse cases and forty-five in the third degree or complete prolapse group

I have been able to check up satisfactorily but 55 of the 100 cases operated upon Forty-two have been examined by my assistant and myself The remainder by family physicians, augmented by personal reports from patients who could not come in person A 50% follow-up has been disappointing to me but it was the best we could do It does not enable me to draw fair comparisons beyond the total number checked over You will observe that the number of interposition operations followed up is greater in proportion than the total list, thirty-eight out of fifty-five

I have combined under abdominal operations the vaginal suspensions, chiefly the Simpson modification of Gillium and Oldhausen, always with plastic work, also one case of complete prolapse of cervix and bladder, original hysterectomy having been done elsewhere. In this case the stump was sutured to the abdominal wall, followed by vaginal plastic work In dividing the results into symptomatic and anatomical groups, the number of cases is again not great enough to be conclusive but is indicative Thirty-two out of thirty-eight cases submitting to interposition operations were cured of all symptoms Four had definite urinary symptoms One of the cases with urinary disturbances had a feeling of desiring to empty the bladder frequently Another patient had a feeling that the bladder was incompletely emptied although in neither of these cases were the symptoms particularly annoying There were two cases of urinary incontinence. This incontinence occurred before the operation In both of these I did a Kelly sphincter constricting operation in addition to the interposition In both cases patients were improved but not entirely cured. I believe these two cases should not properly be charged against the interposition operation Another one of my patients was conscious of some bearing down in the pelvis when on feet for a long time She is one of the two cases with anatomical defects In another the cervical stump was pointing partway down vagina when patient strained No symptoms There was one failure. I did not see this patient but her physician said she could force cervix down so it appeared at the vulval aperture She is now practically an invalid from other causes and he reports but little inconvenience from her descensus

In the eight abdominal cases, all were symptom-free The vaginal hysterectomies were comfortable. Two patients upon whom the LaForte operation was performed are symptom-free for descensus, although in one case I have been forced to divide the bridge holding the organ back because of uterine bleeding, which reappeared nearly sixteen years after menopause, exciting suspicion of cancer of the uterus I regret to say we found a cancer in the body of the uterus in this patient

I have found it almost impossible to be accurate in my anatomical tables I have used the term "satisfactory" to signify the result in this table Many of the anatomical results seem perfect if that term can be rightfully used in any operation of this kind In many others, there was a slight prominence in the anterior wall where uterus was sutured in the interposition operation Minor defects I have not recorded but have reported them in Table No 3, as comprising practically 20% of cases inspected They were inconsequential and patients were unconscious of their presence I have recorded only the gross defects In one there was a definite sagging of the anterior vaginal wall of which the patient was conscious In the second there was a definite descent of the cervix in upper vagina, causing no symptoms This was the patient referred to in Table No 2 There was one complete failure There were no gross defects in the abdominal group In the vaginal hysterectomies one of the patients has a narrowing of the vagina in the upper part, producing no symptoms at present

Satisfactory		8	
Plastic-Mayo	2		
Satisfactory		1	
Vault vagina narrow			1
LaForte	2		
Satisfactory		1	
Slight descent			1
Totals		45	5

In one of the LaForte operations, the uterus had descended down the gutter on one side but was producing no symptoms The one death reported in Table No 1 was caused by an infection This patient was a fairly good risk although uterus was large. It was one of the cases in which

resection of the uterus seemed necessary Patient suffered no shock of consequence but died at the end of five days from infection

I regret that it has been necessary for me to take this list from a series almost entirely within the past five and one-half years Many of these patients have been too recently operated upon to have the results at the present time final It is quite possible I shall have a greater number of failures than now appear In my experience by far the greater number of failures occur within the first six months and if the patient goes nine or ten months without defect, the chance of failure is exceedingly small To this extent my tabulation will have value My motive, however, has not been to establish a record of symptomatic or anatomical cures but rather to show an adaptability of the interposition operation to a somewhat larger group than is now accepted by most operators

---

THE PRACTICING PHYSICIAN IN PUBLIC HEALTH

By JAMES N VANDER VEER, M D, ALBANY, N Y

The address of the President of the Medical Society of the State of New York before the annual Conference of Health Officers and Public Health Nurses at Saratoga, on June 25, 1929

As President of the Medical Society of the State of New York I bring its greetings to the State Health Department, Health Officers, and Public Health Nurses here gathered, and the appreciation of the Society for the privilege of participating in the discussion of the questions of public health

So much has been accomplished in preventive medicine by our State Health Department as a whole, and its components in the various Counties through you, that congratulations are in order And yet many aspersions have been cast upon the doctor for his apparent lack of interest in the same However, many of you who sit before me now are the same doctors that will sit before me in our own State and County medical meetings and discuss these same questions that come up from the other angles than may be put forth here in such a meeting

While it is unbecoming in a speaker to criticize in a negative manner one who has preceded him on the program, and is also your guest, I am, however, going to be so bold as to crave permission to make the statement that the topic of Dr Wynne's address is self-evident to the doctor, who surely vaccinates in most instances those who have come in contact with a case of smallpox (where allowed by the contacts), and gives prophylaxis to those who are in the same family where exists a case of diphtheria (where permission is granted), and so could examples be spun out to any length to prove that the doctor is alive to preventive medicine and its economic soundness

But—and here lies the crux of preventive medicine—the practising physician cannot expend the time in argument with a recalcitrant mother, father, or grandmother as to why Johnny should be given the Shick test or be immunized when sister Susie has diphtheria His time must be converted into dollars and cents as it is his capital investment, and in the present, the public only sees him as an actor in curative medicine *after* Susie and Johnny have become ill And his efforts are limited in his production of wealth and in work done only by his physical endurance in many instances, and by the brains which he puts into his efforts

Here is the question put in this manner as the doctor sees it If we can convince the *average person,* and the *public* as a whole, that preventive medicine is worth while and pays in dollars and cents, then we have a common ground for all agencies to unite and forward a broad program

The doctor, as an individual physician, is trying here and there to fulfill his part as a member of various health groups, but he acts as an individual, and in many instances because of his desire to fulfill his lay civic duty I am glad to say that also the Medical Society of this State is earnestly endeavoring to do its share to forward this immense movement Through its various committees, in a small way perhaps, it is attempting to spread the gospel of health, but it lacks the essential of that which is most necessary—namely the large finances whereby the public may be reached through the press, such as are at the command of the State, and in the hands of many philanthropic organizations

Its resources are only those from the dues of its own members It has no large gifts to adapt to its program, and under present conditions should not directly accept endowments demanding subservience to a program other than what it, as a Society, might determine As a result its efforts are dwarfed in comparison with those of lay health organizations who yet leave to the doctor the work of rehabilitating those who are weak and are falling by the wayside through disease

Those who are sick and diseased are now occupying and filling the mind of the practising physician, and his work must naturally be at their beck and call But when the education of the public as a mass, and as individuals within that mass, has been accomplished, by more than the mere scratching of the surface as we now see it, the physician will be found as the one who has largely accomplished this result as an individual

in his community, with the help of the other agencies concerned

He has but to be furnished individually in each little hamlet, or large city where he may reside, with the proper educational material as the sinews of war, to teach the public to demand preventive medicine, and then from school children on up through the grownups will our hopes come true.

The failures of such a program somewhere along the battle front are found in the individual physician or local officers of organzations, whose carrying out of orders and plans are failures because of their own inability to forward the general good, and because they cannot deal intelligently with their inferiors or superiors, and should, therefore, as an army, be due for demotion

The successes of such a movement come from unanimity of thought and action, after plans have been made by leaders of broad minds, in correlating all the forces which can and should be brought to bear in this one effort

In this effort of preventive medicine your State Medical Society seeks to play its part, and asks that it be invited in every instance to take its proper place in the great plan now evolving, so that each of its members may know what is expected of him, and may be made to see the just reward which will be his, when the battle has been won Success will be in the proportion that each recognizes the advantages of the ammunition of different types utilized along the whole line

As in an army, officers and men are lost and must be replaced, so is it in a health fight,—to say nothing of the thousands being born every day who must first be taught the primer of good health in the school and in the family, and then be educated as adults to follow naturally the higher problems as those of second nature.

The Medical Society has to educate yearly its fledglings, as must the State through your Health Officers Association educate its new local directors,—and together we must unite to educate those born this very minute as I speak, to a higher degree than are those who are now about to pass to the Great Beyond

This as I see it is our bond of union in such a vast and wellnigh limitless field

EDITORIAL

NEW YORK STATE JOURNAL OF MEDICINE

Published by the Medical Society of the State of New York under the auspices of the Committee on Publication

Business and Editorial Office—2 East 103rd Street, New York, N Y Telephone, Atwater 5056

The Medical Society of the State of New York is not responsible for views or statements, outside of its own authoritative actions published in the JOURNAL. Views expressed in the various departments of the JOURNAL represent the views of the writers.

SEASONAL ACTIVITIES

Medical Societies, like schools and churches, have their seasonal activities Social events are characteristic of the summer work of medical societies County Societies have their outings, and larger groups, such as the Lake Keuka Medical and Surgical Association, combine science and pleasure in a three-day outing shared with the ladies

Recreational meetings have a great value in educational and administrative ways for they afford officers and committeemen the opportunity to explain their plans to individual members, and to make those friendly contacts which vivify and personify the impersonal activities of the medical societies

DOCTORS AND HEALTH AGENCIES

The history of the State Medical Society shows that the medical profession of New York State has always had problems A survey of it shows the evolution of medicine, and demonstrates that certain principles of relationship with other agencies run throughout its organized history There has always been found a solution for the evils confronting organized medicine, and an interesting thing is that the correction of them has come from the medical profession itself influenced only by public opinion

The correct solution of all the present disturbances of the practice of medicine will be found without impairing the position of the medical profession. The medical profession is so essential to the welfare of mankind that no one should be unduly disturbed by anything or all things confronting medical practice today, but rather to be concerned with the correction of them before they produce more than a minimum of disturbance

Dr Ray Lyman Wilbur at the last Annual Congress on Medical Education said that physicians are "the prey of tradition" In the influence of tradition may lie the medical profession's major difficulty in adjusting itself to the new relationships that must ultimately be met by the medical profession If, as Dr Wilbur says, we accept tradition as the name given to the process by which one generation protects its product from change by those who are to follow, we can understand in part at least why the relationship of the medical profession changes so slowly in its attitude toward other health efforts by other agencies and other organizations But, the principles underlying the profession of medicine are the same as they were one hundred years ago Nothing has supplanted the object of the A M A "to extend medical knowledge and advance medical science, to enlighten and direct public opinion in regard to the great problems of medicine" These principles must remain as the basis of all relationship of the medical profession to all health agencies

A large number of medical men are still in the position of isolationists, and are making little definite effort to make use of the features that are common to medicine and to health agencies Should not lay health effort go on with our endorsement, while we are endeavoring to correct its mistakes instead of wasting time in the futile effort to stop it?

The Medical Society of the State of New York took a forward step three years ago when it formed a Public Relations Committee Constructive work has been undertaken by it It has become already an asset to organized medicine The Committee itself has had its own viewpoint enlarged, and has acquired an understanding of the need of a closer relationship between the medical profession and other health effort either by health agencies or by industry The work of this committee should give to the general medical profession a better understanding of the new era in civic medical consciousness and its manifold responsibilities The Public Relations Committee of organized medicine in this State has begun to mark out the pathway that can lead to a real cooperation of professional and lay health work, and a beginning understanding of the conditions upon which they can work together If this is accomplished, it will be a service to health advance unsurpassed by the work of any other committee of organized medicine

There is an industrial revolution in the whole world Nothing is standing still in the business world, or in our national affairs and relationships, or in medicine and health conservation Professor Shotwell of Columbia University, an authority on International Policy, is making extensive contributions to the general subject of Public Relationship," which is equally applicable to medical relationship We have been so inextricably wound up in the past traditions that we have had difficulty in seeing that a new chapter is being written in the cure and prevention of disease in response to public opinion The effort of voluntary organizations to aid in the solution has behind it public support The partial failure of medical practice to distribute adequate service at reasonable cost to a large percentage of the people has stimulated industry to undertake medical service to its employees Would the Standard Oil Company, the Telephone Company, and others be undertaking to provide medical service to their own people if the medical profession had met fully the expected service in the beginning of illness of their employees, that is, if we had been more interested in the prevention of later illness?

Medical leadership in health programs can become powerful only by peaceful cooperation instead of controversy The greatest danger in our public relations is that we have not fully realized that a new era has begun, and that the people have acquired a new sense of their responsibility in advancing welfare, charity, and health When business corporations in increasing numbers hold special meetings to consider these things, giving the reason among others that it pays in a financial way, and then form organizations placing the management of them in the hands of business and civic leaders often men of dynamic personalities, it should suggest to the medical profession that there is developing a force too powerful to ignore, and so potent that if united with medical leadership in its medical administration it will vastly increase the accomplishments of the medical profession and become an asset to all that is best in its objectives

The activity of health agencies and foundations is of itself an indication that there is a new condition confronting the medical profession No one should expect the future of medical relationship to repeat the past It is already different, and it seems reasonable to expect that it will steadily become increasingly different Since we know the past in medicine, and since we should see the present trends in health effort, there is not much excuse if we are some day taken by surprise and find that we are not a part of the readjustment There are forces in health and welfare activities in the world today that were not even thought of a few years ago They are gathering power, and as surely as daylight follows night, these new forces will to an unknown extent influence or disturb the practice of medicine unless we join with them

The problem for readjustment is quite easy On one hand, high cost of medical care, leading to an inadequate service to a large class, and to an organized body that intends to give it, and on the other, encroachment on private practice with economic disturbance We should approach this problem in a spirit of conference, remembering that we have no mortgage on health programs

The problems are nearer a solution than they have been because of just two things 1, lay agencies seem now to recognize that sound health programs depend upon the leadership of those medically trained, and 2, a growing recognition by doctors that they are not organized to carry health programs to the public We must soon bring about this general cooperation or it will be done for us by the force of public opinion

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO

Illegal Practitioners—A quarter century ago the medical societies prosecuted illegal practitioners and received the fines which were imposed What the result was is described in the July, 1904, issue of this JOURNAL

"The past month has been a record one in the number of illegal practicers brought to justice, and up to the time of going to press eight were convicted of practicing medicine, and there are four others that have not been reached for trial The work of the Association has been a matter of favorable comment by the courts, and the complaints resulting from the knowledge of the manner in which these prosecutions have been conducted have increased until now there is an average of one complaint a day

"It is also evident that there should be an amendment to the law under which illegal practicers are prosecuted, fixing the amount of fines which should be not less than $100 for a first offense, and not less than $250 for the second offense, and coupled with a larger term of imprisonment

"With the two new judges on the Special Sessions bench it is evident there is a feeling that smaller fines should be imposed in these cases, and the result of their service upon the bench covering a period of the last three months is very plainly evident in the increasing illegal practice, owing to the fact that these individuals realize that they can well afford to pay a small fine and when brought into court for the second offense perhaps a month later, to pay a slightly advanced fine

"The members of the Court will soon see the added work following these small fines, and though arguments are presented they are taken with the realization that possibly the remarks are influenced by the fact that the Association gets such fines as may be imposed"

MEDICAL PROGRESS

The Heart and the Way in Which It Is Supported During Life.—G Arbour Stephens, writing in the *Practitioner*, May, 1929, cxxii, 5, points to the need of a better understanding of the way in which the pericardium functions as a support to the heart. In disease the normal negative pressure within the pericardial cavity disappears and with it the suction action, so that the pericardium no longer fits closely to the heart and is unable to give it the support it requires In health the shape of the heart, as shown by roentgenograms, is the same whether the subject is in the vertical or the horizontal position, while in disease there is considerable difference Polygrams taken from the same patient in the prone and then in the upright position show a great deal of difference, there being additional waves in the prone position which can be explained only by assuming that they are due to movements of the pericardial fluid caused by disturbance of the negative pressure and the defective suction action Heart sounds, which in a healthy heart are practically the same in both vertical and horizontal positions, have a tendency in patients with heart disease to change as the patient changes position These variations which are found in disease are evidence also of a disturbance of the cardiac lubrication In disease, when the muscle fibers are not working as they should, exudation becomes irregular and the pericardial contents become abnormal The thin-walled auricle is the first to suffer from lack of support and to give evidence of fibrillation These facts suggest the need of a new theory for the causation of fibrillation instead of the one generally accepted. In angina pectoris the sudden increased exudation and the accompanying modification of the tension in the sac causes the agonizing pain The great value of digitalis is due to the distinct effect it has on the contraction of the muscular fibers of the heart and therefore on exudation, which takes place through the coronary vessels, it seems as if all the drugs, such as pituitrin, adrenaline, and the nitrites, owe their success to the effect they have on the capillary circulation A heart which has poor and inadequate lubrication is a heart whose myocardium and myocardial vessels are in bad condition The methods here suggested may be of value in the early diagnosis, classification, and prognosis of heart disease

Cardiac Pain.—In a discussion of the nosology and clinical associations of cardiac pain, Robert L Levy shows that pain in the region of the heart may be a symptomatic manifestation of many pathological states It may be encountered in affections of the coronary arteries or of the aorta, in cardiac valvular disease, in pericarditis, in poisoning of the heart, as by tobacco, coffee, or tea, in disorders of the hematopoietic system, in endocrine disorders, or in cardiac neuroses, or it may be of undetermined pathogenesis Perpetuation of the name originally given to the condition, and the concept of angina as a clinical entity, has resulted in confusion and disagreement as to its precise meaning It is, therefore, suggested that the term "angina pectoris" be abandoned Pain resulting from disturbances in the region of the heart may best be described as "cardiac pain" In making a complete cardiac diagnosis, this should be qualified by a statement as to the probable structural and functional changes with which the pain is associated The conception of pain as a symptom will make for better diagnosis, for rational therapy, and for more accurate prognosis Therapy must be directed toward correcting or alleviating the basic disorder Until more is known concerning the mode of production of pain and its sensory pathways from the heart, cervical sympathectomy should be performed only on patients who suffer intensely, who have not improved under well directed medical care, and who, in the opinion of the physician, will stand surgery without undue risk Patients with coronary disease are poor surgical risks, and it is in this group that the worst sufferers are found The paravertebral injection of alcohol into the posterior nerve roots is an uncertain procedure and is not without hazard.—*American Heart Journal*, April, 1929, iv, 4

Blood Glands and Blood Pressure.—F Kisch of Prof Wenckebach's Medical Clinic, Vienna, begins his article with the blood pressure in Graves's disease. He tested 84 patients, chiefly women with a pronounced type of the disease, with some anticipation of finding a high incidence of hypertonia, but this was present in no more than 30 of them, while but one showed hypotonia and the balance were normal in this respect There was no definite relationship between basal metabolism and blood pressure, although others, as Mannaberg, have noted some connection between high tension tachycardia and increase of basal metabolism above the average The author's research in certain patients with other than hyperthyroidism showed that hypotonia may also be associated with an increased basal metabolism, notably

in valvular heart disease with decompensation He is quite satisfied from numerous quoted figures that blood pressure has no necessary association whatever with the rate of basal metabolism Does low blood pressure stand in any definite relationship with hypothyroidism? Barach found that such an association occurred in the great majority investigated and the author has partially confirmed this statement Roberts who tested 350 cases of miscellaneous patients with low blood pressure found but a small percent with disease of the endocrine glands The contrast between the thyroid and adrenals in this respect is marked, for in Addison's disease hypotonia is the rule The author makes a category of hypotonic and asthenic subjects, which is much broader in scope, in which permanent hypotonia is one of a number of symptoms, but if other symptoms are reckoned as essential, as headache, constipation, insomnia, enlarged tonsils and lymphatics, lymphocytosis, etc, the percentage of those showing notable hypotonia is less than 40 This large group of patients then cannot owe their condition to adrenal insufficiency although the latter may be a factor—at least the term "hyposuprarenal constitution" has been proposed to denote it—*Klinische Wochenschrift,* April 16, 1929

The Rapid Reduction of High Blood Pressure in Acute and Dangerous Cases—A Graham-Stewart states that many cases of chronic hyperpiesis develop at times, secondary to such states as alimentary toxemia, deficient elimination, and psychological unrest, a condition in which a grave load is superimposed on a chronically high pressure Such added loads threaten the life of the individual from severe and possibly fatal hemorrhage These states are amenable to dramatic improvement on the plan of treatment outlined It is highly important that all the patient's mental anxiety be allayed in a definite and confident way For several weeks the diet should be as sparing as possible and should consist of carbohydrates, fruit, and vegetables

Calomel is given for two or three successive nights—an eighth of a grain every half hour for eight doses—followed in the morning and thereafter every morning by a mixture of magnesium and sodium sulphate sufficient to produce genuine catharsis Equally important is the use of sodium bromide, 15 grains three times a day for a week To this is added 7 to 10 grains of ammonium hippurate In the presence of a dangerous height of the pressure tablets are given containing 2 grains of lithium hippurate, 1 grain of sodium nitrite, and 1/200 of a grain of nitroglycerin As an alternate to this a good prescription is Sodium nitrite ½ 2 grains, ammonium hippurate 7-10 grains, sodium bromide 10-15 grains, spirit of chloroform 10 minims, collosol iodine 1 drachm, and distilled water to 1 ounce This is given three times a day after food, and well diluted Intestinal detoxication may be assisted by giving 3 ounces of liquid paraffin a day in divided doses and 2 ounces of kaylene saline twice daily In the author's experience venesection is of little and brief value—*The Practitioner,* May, 1929, cxxii, 5

Transitory Disorders of the Arterial Tension—Ch Achard discusses arterial hypotension and hypertension, of both the temporary and critical types The former may be recognized by eliciting the white line of Sergent Clinical types are the Stokes-Adams syndrome, ordinary syncope, hemorrhagic and miscellaneous forms encountered in the course of various diseases While traumatic shock is often associated with loss of blood a fall of blood pressure also takes place in non-hemorrhagic shock, this including also the so-called delayed or toxic shock Various poisonings, chloroform inhalation, and so-called protein shock are also attended by fall of blood pressure A different type of hypotension which is more protracted and not very pronounced is seen in acute febrile affections, and from this it is but a step to permanent low tension as seen in a variety of chronic diseases and notably in pulmonary tuberculosis, heart diseases of certain kinds, Addison's diseases, etc Essential hypotension without known causal factors is a well recognized condition In all forms adrenaline is indicated with the proper casual remedies The opposite condition of transient hypertension is not so readily formulated into groups Crises of this condition have been described especially by Pal, for example in lead colic, in the gastric crises of tabes dorsalis, in renal diseases, etc A special form figures in puerperal eclampsia, leading up to the convulsions In some subjects who would ordinarily be set down as victims of permanent hypertension the condition is really one of critical attacks only Here would fall certain cases of angina pectoris Authorities like Vaquez, Mackenzie, and other cardiologists have described various special types of transitory hypertension, largely discovered by pressure-recording apparatus—*Le Progrès Medical,* April 13, 1929

Local Treatment of Burns—Dr E Makai discusses this subject by remarking on the present vogue of the ointment treatment This consists in reality of the old oil dressing and numerous solid substitutes, medicated or not The author, however, is critical of the ointment treatment to the complete exclusion of dry powders and wet compresses All of these

measures have the power of reducing the pain by exclusion of the atmospheric air, but we are entitled to a more rational and studied plan of management based on filling all the indications Pain may be the first symptom to offset, but we have to bear in mind that much dead tissue is to come away, and that is long as this is undisturbed toxic substances may be absorbed Moreover this tissue is an ideal culture medium for bacteria With the elimination of the dead tissue regeneration must be stimulated or at least favored It does not seem to the author that any one stereotyped plan should be followed, for at certain stages of burns wet dressings are preferable, at others dry dressings and at still others ointments Much also depends on the location, area, and depth of the burn, the age of the patient, and so on Loose wet dressings, including the permanent bath, are indicated under certain conditions, but on account of the maceration which follows, regeneration may be impeded It should therefore be well to alternate wet applications with dry dressings, and eventually to cut out the former entirely in favor of the latter Epithelization does much better with dry dressings The evil of dry dressing, which makes it necessary to resort to moist ones, is the formation of a crust composed of the powder and the wound secretion, which in turn favors the accumulation of secretion beneath the crust Hence the problem is often what to avoid in the treatment of burns—avoid crusting on the one hand, maceration on the other In the healing stage petrolatum spread thinly on gauze is useful —*Münchener medizinische Wochenschrift,* April 5, 1929

Non-Tropical or Indigenous Sprue —In the literature of sprue there have appeared from time to time references to the occurrence of indigenous sprue in persons who have never left the confines of Northern Europe Recently Thaysen has reported a series of cases which he discovered in Denmark, and which he describes as "Non-Tropical Sprue" Philip Manson-Bahr has questioned the diagnosis because of the relatively small size of the stool and the absence of accompanying anemia He made the statement that he would apply the most stringent and searching tests before he admitted that any suspicious case occurring in England was an example of true sprue He now reports a case which he has watched for five years and which he believes is a case of true tropical sprue originating in England The patient, a woman, 28 years of age, suffered from vomiting, diarrhea, and rapid loss of flesh The stools were of enormous size, frothy and of a sour odor Aphthae of large size appeared in the mouth The abdomen was doughy and distended, the skin inelastic and dry, and the area of liver dullness distinctly diminished There was anemia of the typical kind and a slight leucopenia Under the accepted treatment—milk diet, rest, and nursing — great improvement took place and she regained her former weight Two years later, after the birth of a fourth child, there was a relapse, with the typical symptoms, and during the next two years occasional relapses occurred After a severe relapse pernicious anemia developed, which responded well to Sir James Cantlie's meat dietary, recovery being complete There have been no symptoms for the last four years Manson-Bahr reports this case in view of the possibility of others of a similar nature being encountered in non-tropical countries —*Journal of Tropical Medicine and Hygiene,* May 1, 1929, xxxii, 9

Gas Poisoning in the Industries —Prof H Zangger contributes the third of a series of articles on this subject and touches incidentally on gas explosions With the rapid development of new industries not enough heed is paid to new possibilities of accidents He mentions the explosive motor gases connected with the automotive industry, the dangers of explosions unforeseen in connection with general catastrophes, mentions by name a large number of poisonous suffocating bodies which might in theory be liberated and the optimum conditions for their liberation We do not however see any allusion to nitrogen tetroxide nor explosive *x*-ray films in this connection, perhaps because this subject is not, strictly speaking, connected with industry directly Most of the author's text is devoted to other types of gas poisoning in which there is no explosive liberation but only a steady absorption with the development of a certain amount of tolerance In his discussion on first aid the subject of explosions naturally comes to the fore and he mentions some recent catastrophes in which phosgene and carbon monoxide were the gases accused Much more space is given to prevention and this consists largely in the use of the gas mask, especially the so-called filter mask But experience with the entire subject of mask protection has been shocking, in other words the presence of gas masks in a plant gives only a false sense of security, based on theoretical grounds —*Schweizerische medizinische Wochenschrift,* May 4, 1929

The Chlorides in Nephritis —F Rathery states that since the publication of the researches of Widal, Achard, and others a diet poor in chlorides has been daily prescribed in Bright's disease This diet, given indiscriminately, has become a cure-all, which is an evil for in some nephritics this regimen not only does no good but is positively injurious Man

in valvular heart disease with decompensation He is quite satisfied from numerous quoted figures that blood pressure has no necessary association whatever with the rate of basal metabolism Does low blood pressure stand in any definite relationship with hypothyroidism? Barach found that such an association occurred in the great majority investigated and the author has partially confirmed this statement Roberts who tested 350 cases of miscellaneous patients with low blood pressure found but a small percent with disease of the endocrine glands The contrast between the thyroid and adrenals in this respect is marked, for in Addison's disease hypotonia is the rule The author makes a category of hypotonic and asthenic subjects, which is much broader in scope, in which permanent hypotonia is one of a number of symptoms, but if other symptoms are reckoned as essential, as headache, constipation, insomnia, enlarged tonsils and lymphatics, lymphocytosis, etc, the percentage of those showing notable hypotonia is less than 40 This large group of patients then cannot owe their condition to adrenal insufficiency although the latter may be a factor—at least the term "hyposuprarenal constitution" has been proposed to denote it—*Klinische Wochenschrift*, April 16, 1929

The Rapid Reduction of High Blood Pressure in Acute and Dangerous Cases—A Graham-Stewart states that many cases of chronic hyperpiesis develop at times, secondary to such states as alimentary toxemia, deficient elimination, and psychological unrest, a condition in which a grave load is superimposed on a chronically high pressure Such added loads threaten the life of the individual from severe and possibly fatal hemorrhage These states are amenable to dramatic improvement on the plan of treatment outlined It is highly important that all the patient's mental anxiety be allayed in a definite and confident way For several weeks the diet should be as sparing as possible and should consist of carbohydrates, fruit, and vegetables

Calomel is given for two or three successive nights—an eighth of a grain every half hour for eight doses—followed in the morning and thereafter every morning by a mixture of magnesium and sodium sulphate sufficient to produce genuine catharsis Equally important is the use of sodium bromide, 15 grains three times a day for a week To this is added 7 to 10 grains of ammonium hippurate In the presence of a dangerous height of the pressure tablets are given containing 2 grains of lithium hippurate, 1 grain of sodium nitrite, and 1/200 of a grain of nitroglycerin As an alternate to this a good prescription is Sodium nitrite ½ 2 grains, ammonium hippurate 7-10 grains, sodium bromide 10-15 grains, spirit of chloroform 10 minims, collosol iodine 1 drachm, and distilled water to 1 ounce This is given three times a day after food, and well diluted Intestinal detoxication may be assisted by giving 3 ounces of liquid paraffin a day in divided doses and 2 ounces of kaylene saline twice daily In the author's experience venesection is of little and brief value—*The Practitioner*, May, 1929, cxxii, 5

Transitory Disorders of the Arterial Tension—*Ch Achard* discusses arterial hypotension and hypertension, of both the temporary and critical types The former may be recognized by eliciting the white line of Sergent. Clinical types are the Stokes-Adams syndrome, ordinary syncope, hemorrhagic and miscellaneous forms encountered in the course of various diseases While traumatic shock is often associated with loss of blood a fall of blood pressure also takes place in non-hemorrhagic shock, this including also the so-called delayed or toxic shock Various poisonings, chloroform inhalation, and so-called protein shock are also attended by fall of blood pressure A different type of hypotension which is more protracted and not very pronounced is seen in acute febrile affections, and from this it is but a step to permanent low tension as seen in a variety of chronic diseases and notably in pulmonary tuberculosis, heart diseases of certain kinds, Addison's diseases, etc Essential hypotension without known causal factors is a well recognized condition In all forms adrenaline is indicated with the proper casual remedies The opposite condition of transient hypertension is not so readily formulated into groups Crises of this condition have been described especially by Pal, for example in lead colic, in the gastric crises of tabes dorsalis, in renal diseases, etc A special form figures in puerperal eclampsia, leading up to the convulsions In some subjects who would ordinarily be set down as victims of permanent hypertension the condition is really one of critical attacks only Here would fall certain cases of angina pectoris Authorities like Vaquez, Mackenzie, and other cardiologists have described various special types of transitory hypertension, largely discovered by pressure-recording apparatus—*Le Progres Medical*, April 13, 1929

Local Treatment of Burns—Dr E Makai discusses this subject by remarking on the present vogue of the ointment treatment This consists in reality of the old oil dressing and numerous solid substitutes, medicated or not The author, however, is critical of the ointment treatment to the complete exclusion of dry powders and wet compresses All of these

LEGAL

By Lloyd Paul Stryker, Esq

LEGAL LIABILITY FOR MEDICAL SERVICES

It is important for physicians rendering services at the request of a person other than the patient, to make inquiries as to who will be responsible for their compensation The mere fact that a blood relationship exists between the patient and the person who requests the physician to render the services, does not of itself render that person liable to the physician for the services so rendered It cannot be safely assumed by the physician that the person at whose request he renders services to a patient will necessarily be responsible for the value of the services rendered

In one case which was before our Court of Appeals for decision, an action was brought by a physician to recover compensation for medical services rendered by him in attending and prescribing for the daughter of the defendant while she was sick at the defendant's residence The value of the services was admitted, and the issue litigated was whether the defendant was liable to pay therefor The patient was a married woman, the wife of one John Jones She had been sick at her own residence about three months, when, because of the wish of her mother, she was brought to the house of her father, the defendant in the action. The defendant had employed two other physicians before the plaintiff was called in

It appeared from the evidence that about a month after the patient had been in the home of her mother and father, a person came into the the plaintiff doctor's office, who was unknown to him, but who he afterwards discovered to be the husband of the patient, and this person told the plaintiff that the defendant was desirous of having him see his daughter the next day The doctor accordingly went to the defendant's residence, saw the patient, examined the case and received from the defendant a case history On the trial the doctor testified that on each day that he saw the patient, her father, the defendant, was present. All the directions with respect to the treatment of the patient were given by the plaintiff to the defendant father It was also established that the plaintiff had sent his bill for services to the defendant. The defendant testified that he never employed the plaintiff nor did he request any person to call him He denied that he was present during the consultations or that he received any instructions from the physician In holding that the father was not legally obligated to pay the physician for the services rendered to his daughter, the court said

"The plaintiff must then rely upon having shown such facts and circumstances as will sustain the law in implying therefrom a promise by the defendant.

"Prominent among those which are relied upon is the fact that the patient was the daughter of the defendant And were she a daughter for whom, by reason of her minority and dependence upon him, the defendant was under a natural obligation to provide necessaries, this fact would be strong, with others to be mentioned, to sustain an implication of a promise *** But the relations between the defendant and her were not such as that there was upon him such obligation She was much past her majority; she was married, she had lived with her husband and their children, separately from her father, in a house of their own, she was, at that time, living with her husband and their children Her husband was bound primarily to supply for her all that she needed Though she was brought from their own house to that of defendant, it was at her mother's instance and for a special purpose, that of having her under the immediate care and attention of her mother No reason for the removal, other than this, is shown This did not impose upon him any greater general obligation than existed before. Nor did it give ground for the law to imply a special obligation. Again, the interest exhibited in the case by the defendant to the plaintiff, his recital to him of a history of her trouble, his presence when the plaintiff made his professional calls, alone and in consultation, his receiving directions as to treatment, his recognition, to others, of the fact that the plaintiff was in attendance, his recital, to others, of the plaintiff's opinion of the patient's condition, and his knowledge of the frequency and length of continuance of the professional visits of the plaintiff, without any disclaimer on the part of the defendant of liability, are relied upon as circumstances making a basis for an implication"

"It is true that a person may not avail himself of the benefit of services done for him without coming into an obligation to reward them with a reasonable recompense But he cannot be said, in the meaning of the law, to avail himself of services as so done when they are not for his individual benefit, nor for that of any one for whom he is bound to furnish them The acquiescence of one in the rendering of service or

is intended by nature to eliminate a certain amount of saline matter daily, at least half of which is sodium chloride, and it is unnatural to cut this substance out of the diet save for some very special reason If there is an unnatural retention of this salt then we must get rid of the surplus With kidneys damaged the latter backs up in the blood and tissues and water retention may also be present. We may wave the question of whether the chlorine or sodium is the dangerous element and be content to know that in chloride retention, with or without edema, the salt-free diet is of marvelous value, thanks to Widal But with nephritis unaccompanied by salt retention the withholding of salt from the diet gives rise to a train of symptoms comprising asthenia anorexia, vertigo, even vomiting at times Salt privation has been much studied in animals and normal human subject and its syndrome is well-known A certain degree of privation of salt in certain nephrities has led to extreme emaciation, low blood pressure, subnormal temperatures and a high alkaline reserve There is also nitrogen retention All of these symptoms soon disappear or improve on the addition to the diet of a little salt L Blum has described a uremia or azotemia from lack of salt and we see that this condition may develop alike with too much or too little salt in the food It is obvious that the blood of the nephritic should always be examined for chlorine and the treatment based on such findings —*Bulletin de l'Académie de Médecine*, April 16, 1929

Congenital Debility and Its Conquest—A Peiper of the University Pediatric Clinic, Berlin, refers to the mortality the first few days post partum, not including the cases where death results from some definite lesion In some cases in which death is attributed to a lesion the actual cause must be set down as congenital weakness Naturally the premature children form a special class The problem of hemorrhages is of special significance, for death is commonly attributed to such accidents, especially when seated within the cranium However it is not always easy to show the mechanism of death in these cases, for the part of the encephalon most involved may not be of vital importance to the infant Death need not result from hemorrhages in the cortical area but if these occur in the vicinity of the medulla they are incompatible with survival In general a hemorrhage may cause death directly or indirectly or may not be responsible for the death at all. The former custom in the case of a dead premature child which had succumbed after surviving birth was to assign the death to congenital debility Unless an autopsy has been made, nothing is gained by the more refined diagnosis of traumatism of birth, cerebral hemorrhage, or the like In cases of suspended respiration there may have been some injury done by efforts at reanimation, or the early care of the newborn may have been defective, permitting chilling, etc The problem of combating the mortality of the newborn must resolve itself into special minor problems Thus there is one premature to every 10 children born at term and much depends on the age of the premature infant The effort should be first to prevent the premature expulsion of the child, the causes of which should be known Thus more premature children are born among the proletariat than among the sheltered classes and this is due largely to defective nourishment —*Deutsche medizinische Wochenschrift*, April 26, 1929

Bang Infection—Prof Poppe, a veterinary surgeon of Rostock, refers to infection of mankind from the infectious abortion in cattle, cases of which are rapidly accumulating Such transmission was formerly denied for had it been possible, it was said, it would have been frequent, because the milk of such infected cattle is subject to consumption by large numbers of the public Laboratory and experimental work by a number of investigators showed finally that the active organism accused was identical with or closely similar to the *Micrococcus melitensis* and that the disease itself was analogous to Malta fever In order to distinguish the two diseases one should go on the supposition that Malta fever is due primarily to the milk of infected goats while Bang infection is communicated in various ways by the cow and pig Thus far we have no generic term to denote both diseases The earliest cases of Bang infection were found in the United States and occurred in children who drank raw milk Later, cases were recognized in the Mediterranean countries but apparently without any confusion with Malta fever In the final summary to his article Poppe apparently chooses the term undulant fever to designate both diseases jointly or perhaps the Bang infection only Suspicion should be aroused when individuals who run a temperature are able to be about with little disturbance of the general health, but it is necessary to exclude a number of other maladies comprising typhoid, paratyphoid, malaria, grippe, and sepsis In all such cases the first step has always been to make a Widal test, and now we should add to the latter an agglutination test with a strain of the *Brucella abortus* or Bang bacillus The next step is to trace the history of exposure, if any, to cattle and their products or to swine. The author admits that the relationship between the two forms of undulant fever is still far from clear, being based chiefly on the identity or non-identity of the offending organisms —*Münchener medizinische Wochenschrift*, April 26, 1929

LONDON LETTER

THE GENERAL ELECTION

This letter is being written during the "turmoil" of a general election but a great change has taken place in the exciting times mentioned by Charles Dickens To-day no visitor to London would imagine anything out of the ordinary was taking place, and yet the most "experimental" election England has even seen is in progress For in this election for the first time a wholesale enfranchisement is in force, and everyone over twenty-one, male and female, has a vote The new law gives the vote to an additional 4,000,000 women and the result is that female voters outnumber the male voters by nearly 2,000,000 How these votes will be cast is entirely uncertain It is probable that until the novelty wears off the women will vote in large numbers, and may well decide the issue To which of the three parties the majority of the new votes will go seems to be a mystery even to the party organizers, and we must wait and see We men are always rather inclined to belittle our womenkind's political acumen, but history does not show that masculine wisdom has been very conspicuous in the conduct of international relations, and we have little to flatter ourselves upon The modern young lady does at least know her own mind, and is not slow to express her views One wonders what Oliver Wendell Holmes would have thought of it all, and how he would re-write his well-known lines

"The freeman casting with unpurchased hand
The vote that shakes the turrets of the land"

CONGRESS OF MILITARY MEDICINE AND PHARMACY

The Fifth International Congress of Military Medicine and Pharmacy has just met in London and proved a great success It was presided over by Sir Matthew Fell, the Director General of our Army Medical Services, and no better nor more active President could be desired It is sad to think that this genial giant, in the very prime of life, must, by the inflexible rules of the Service, resign his post next September, and retire from work he loves so well We shall miss him and his almost fanatical fear of after-dinner speaking The two principal functions connected with the Congress were the reception at the Royal College of Surgeons, and the banquet at the Guildhall At Lincoln's Inn Fields I found the fine rooms of the College filled by a polyglot assembly wearing every uniform known to civilization We all seemed to think, or perhaps to hope, that each visitor, whatever his nationality, could speak French, and with one accord we attacked everybody we did not know in that seductive but difficult language I have no doubt that much excruciating French was spoken that night by both sides, but everything was very jolly and informal At the Guildhall, Lord Moynihan, newest of peers and most gifted of orators, gave an address which was eloquent even for him from whom we expect so high a standard He paid a well-deserved tribute to Florence Nightingale, the great founder of scientific nursing, to whose work in the Crimean War the whole world is indebted for nursing as we know it I cannot help regretting that we know so little, and rarely hear, of one who lived nearly 200 years before Florence Nightingale, and founded a great hospital and did fine work for her country Jeanne Mance left her native country of France to cross the Atlantic to Canada, and in the thirty years of her too short life (1642-1673) originated a great nursing sisterhood in that country and founded the Hotel-Dieu in Montreal I often think of the picture of her, mounted on a very spirited grey palfrey, turning her back determinedly on the castellated walls of her ancestral home, and setting out, against her parents' wishes, on the Great Adventure The modern girl is not so modern, after all!

INTERSTATE POST GRADUATE ASSEMBLY

The Interstate Post Graduate Assembly of North America has just concluded a flying visit to London, and we have been doing our best to show our visitors how much we appreciate these pilgrimages Sir John Bland-Sutton welcomed the members in a delightful speech in which he compared the difficulties of the early days of scientific investigation with the ordered progress of the present. Sir John has always something to say which is worth remembering, and savors instruction with a humor entirely his own, but I do not think he will ever better his reference, in an address to the same Assembly some years ago, when he compared his audience to a flock of migrating birds, the mystery of which phenomenon he had never been able to solve

H W Carson, F R C S

benefit to another, not entitled to call upon him therefor, is not equivalent to an acknowledgment that it is rendered at his request So far as legal responsibility was concerned, the defendant, though the father of the patient, was a stranger to her and to her necessities He could neither require of her, nor be required upon by her It has been held that a special request by a father to a physician to attend upon his son, then of full age but lying sick at the father's house, raised no implied promise on the part of the father to pay for the services rendered *** A physician attends in every case on request, that fact alone is not sufficient for the inference of a special contract *** Still less, where there has been no special request by the father to the physician, and no more than acquiescence in his calls It was the duty of the plaintiff to know or to learn the true legal status of the patient, and what were her true legal relations to the defendant, and he cannot rely upon any seeming legal and necessary dependence of her upon him In the case of minor children, even, the law imposes this duty upon those who would furnish them with necessaries, relying upon the credit of their fathers and seeking to charge them *A fortiori*, is it so in the case of an adult married daughter living with her husgand so that all these circumstances, upon which stress is laid in behalf of the plaintiff, afford no support to his claim

As it would be unnatural for the parent of an invalid child, though legally emancipated, or for an intimate and confidential friend of her, not to know the rise and course of her malady, not to be interested in the state of it as disclosed at any time to skilled inspection, not to be so anxious as to be in waiting when scientific skill was to be applied for its cure, not to be ready to receive directions for treatment in the intervals, so it is not to be implied in the one case more than in the other that, from these manifestations, because unaccompanied with an express repudiation of liability, a liability may be implied They are to be referred to natural affection and friendly sympathy, rather than to an acquiescence in the rendition of a personal benefit, or counted as acts done under a sense of legal obligation"

In another case in the same court the doctor was called one evening by a woman who told him that her daughter, a married woman, was seriously ill and asked the doctor to come to see her The doctor replied that he could not go without the consent of the daughter's husband This consent was not obtained at that time, but about two weeks thereafter the doctor had an interview at his office with the mother and her son-in-law She introduced her son-in-law to the doctor and in his presence asked the doctor if he would go up to see her daughter and the doctor said he could He thereupon went with the mother and made an examination of the patient. After the examination he informed the mother that he would like to withdraw from the case because of the particularly grave condition of her daughter, to which the mother replied "Doctor, you have been my friend, you have attended my family, you have attended my husband and our children, and I beg of you, for God's sake, don't desert Maude" (Maude being the name of the patient) The doctor thereupon consented to treat the patient and was in continuous attendance upon the patient until her death, which occurred about two months after his first visit The doctor rendered a bill for his services to the mother, and when payment was refused he began action against her In holding that he was not entitled to recover, the Court of Appeals said

"The only question upon this appeal is whether the defendant came under any obligation to the plaintiff That turns upon whether the law will imply a promise on her part to compensate him If we might assume the existence of a moral obligation, that would not determine that a legal, or enforceable, obligation existed The general rule, that, where a person requests of another the performance of services, which are performed, the law implies a promise by the former to pay their reasonable value, has no application in the case of a physician, rendering professional services to a third person, if the relation to the patient of the person, who requests them, be not such as imports the legal obligation to provide them"

"A physician, in the absence of a special contract, may recover upon an implied agreement to pay for his services *quantum meruit*, when they have been rendered at the request of the patient, or of a person who, in the eye of the law, is regarded as being under a legal obligation to provide such professional services for the patient, such as a husband, or the parent of a minor child In the present case, according to the plaintiff's testimony, he refused to attend the patient until the husband had consented, which may be said to be a recognition, at least, of the marital relation, with its consequent responsibility, or liability It, certainly, followed that when the husband's consent was given, an obligation arose on his part to pay the reasonable value of the services which the plaintiff might render"

The court held that there being no express promise by the defendant to pay, the circumstances did not warrant any implied promise on her part

The attention of the medical profession should be directed particularly to the concluding sentence in the court's opinion, which reads as follows

"It would be a simple matter, in cases where the physician is called upon to attend a person, at the instance of some one not standing in a responsible relation to the patient, to inform himself as to whom he shall look for his compensation"

THE DAILY PRESS

MEDICAL LEADERSHIP

Much has been written on the subject of leadership Instruction in leadership is given to varied classes of employees ranging from executives at the head of great corporations to boy scouts on the theory that the ability to lead may be developed The *New York Times* of July 5 has an editorial on the elements of leadership, which says·

"A Chicago University professor has been applying exact scientific methods in trying to find out whether there is such a distinct quality in man as 'leadership' The word and the thing have been thrown at us in countless ways Even babes in arms have been minutely studied to see if they bore in their tiny bodies and dawning minds promise of becoming leaders of mankind But now we are told after these painful researches that 'there ain't no sech a thing' The Chicago professor has studied sixty men, ranging from the heads of gangs now in prison, to soldiers and business men who were offered as fine specimens of leadership But they all baffled inquiry Nothing could be found in them, any more than Mark Twain's man could find in the Jumping Frog, to show superiority over their fellows

"The conclusion is that this mysterious gift of leadership is largely a delusion Fortunate environment and lucky opportunities count much more than latent ability So runs the Chicago professor's logic, but there is one evident weakness in it The man who succeeded must have had at least the native ability to seize the happy skirts of circumstance when they passed him

"There is the little indefinable something in one individual that enables him to open his oyster, when it is presented to him, while another merely fumbles at it. This may not be wholly luck or exclusively leadership, but the blend of the two is necessary to success"

The Medical Society of the State of New York is searching for men who will be leaders in County Medical Societies The editors suggest that leaders are those who do things according to the plan of the preacher in the Book of Ecclesiastes "Whatsoever thy hand findeth to do, do it with thy might." Lincoln said that he had known many great men and all of them seemed like the rest of us, except in their practical knowledge of one or two subjects which made them leaders

---

THEY SAY

Next to the joy of discovery is the elation that follows a logical explanation of a mystery James J Montague, in the department "More Truth Than Poetry" in the New York *Herald-Tribune* of June 21, explains the light of fireflies in a way that is entirely satisfactory to his five-year-old boy.

Lightning Bugs

The lightning bugs, long years ago,
Were not with flickering beams aglow,
But journeyed forth their food to find
Like others of their fluttering kind,
Not in the watches of the night,
But in the brilliant broad daylight.
However, when the creatures found
That there were hosts of birds around
Between the dawn and set of sun
And fond of insects, every one
They wisely chose to wait till dark
Before they started forth to lark
Along the singing river's edge
And past the orchard and the hedge.
But bugs more safely fly at night
If each one has a tiny light.
And so beneath their wings they bear
A torch that twinkles in the air
The while their lofty way they thread
When all the birds have gone to bed
And bugs cannot be caught for food
To give a songster's hungry brood.
It may perhaps occur to you
That the foregoing is not true.
All I can say is, it was told
To me by Bill, who's five years old

To this alluring tale absurd, we add our editorial word A lot of bunk that folks believe will quickly clear up and relieve their rheumatism, pains, and colds comes from the brains of five-year-olds

NEWS NOTES

HEALTH OFFICERS' CONFERENCE

The twenty-eighth annual Conference of Health Officers and the eleventh annual Conference of Public Health Nurses of the State of New York had a larger attendance this year than ever before in its history While the program was good throughout there were several striking features Among them was the splendid address of Governor Roosevelt who said that there had been a great change in public health in forty years and he wondered how far it would lead us in the next forty years He said, "Every state has undertaken the care of the health of its people The state has a right to see that the health of its people is as good as it can be The public has a right to have health and it is the right of the state to control in health matters Individual doctors are not to blame for the lack of public health because they have not the machinery at hand to make their efforts effective" Governor Roosevelt hopes that we will have a health census in this country something as they now have in Australia All health effort in the state is now undermanned and underpaid

The Governor's speech was splendidly received and showed an unusual interest in health matters and an unusual grasp of how health can be improved

Among the papers there were two of very practical value—one on, "Practical Epidemiology" by Dr Frank W Laidlaw, District State Health Officer and another by Dr Arthur T Davis, County Health Officer of Suffolk County on, "A County Health Department in Operation"

There were many other excellent papers and excellent discussions of them As a whole, it seems fair to say that this conference was better than any other among the very successful conferences held yearly by the New York State Department of Health

W H Ross

FRANKLIN COUNTY

The regular semi-annual meeting of the Medical Society of the County of Franklin was held in the John Black Memorial Room in Saranac Lake, June 12, 1929 Luncheon was served at the Hotel Saranac, after which a business session was opened at 2 p m The following members were present Dr P F Dolphin, President, Dr G F Zimmerman, Secretary-Treasurer, Dr F F Finney, Censor Doctors Trembley, Stamatiades, Packard, Kinghorn, Van Dyke, White, H B Brown, Heise and Baldwin Visiting doctors, L W Gardner, Saranac Lake, F J Abschul, Long Branch, N Y

The following nominating committee was named by the President —Drs Finney, Packard and Heise The following nominations were submitted and approved,—President, E S Welles, Saranac Lake, Vice-President, P E Stamatiades, Brushton, Secretary-Treasurer, G F Zimmerman, Malone, Censor for three years, G C de Grandpre, Tupper Lake

Dr R L Strong of Bloomingdale was elected a member

Dr C C Trembley reported on the meeting of the State Medical Society

Drs Kinghorn, Baldwin and Trembley were appointed a committee to draft resolutions on the deaths of Drs E R. Pfarre and G M Abbott

After some discussion regarding the advisability of a uniform medical and surgical fee for Franklin County, it was decided to leave the matter in abeyance, and it was moved by Dr Trembley and seconded by Dr Finney, that the old fee bill of 1919 be abrogated Carried

At the scientific session the following papers were read and discussed —

(1) "Colds and Tuberculosis," Dr F H Heise, Saranac Lake Discussed by Dr Packard

(2) Case Report, "Infantile Intussusception," Dr P G Stamatiades, Brushton Discussed by Drs Dolphin and White

(3) "Tuberculosis in the Practice of the General Physician," Dr E N Packard, Saranac Lake Discussed by Drs Kinghorn and Heise

(4) "Some observations on Eye, Ear, Nose and Throat work in General Practice" Dr G F Zimmerman, Malone. Discussed by Drs Beattie, Brown, Dolphin, and White

Meeting adjourned

G F Zimmerman, *Secretary*

BOOK REVIEWS

INTERNATIONAL CLINICS. Edited by HENRY W. CATTELL, A.M., M.D. Thirty-eighth Series, Volume IV. Octavo of 312 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, 1928.

This volume contains some of the lectures on the diseases of old age delivered last October at the New York Academy of Medicine. Radiotherapy in malignant disease is well presented by Pfahler, while angina pectoris is ably discussed by Harlow Brooks. The menace of circulatory insufficiency in obesity, particularly when emphysema and bronchitis are associated with it, is elucidated by Barker. Anders deals with immunization. Epilepsy is analyzed by Brock. The differentiation between syphilitic and non-syphilitic lesions of the skin is made clear by Howard Fox. This is to name only some of the articles and not to imply that the others are not up to their high standard.

A. C. J.

MODERN PROBLEMS IN NEUROLOGY. By S. K. KINNIER WILSON, M.D., B.Sc. Octavo of 364 pages, illustrated. New York, William Wood and Company, 1929. Cloth, $6.00.

The subject matter is spread over 15 chapters and relates to many obscure neurological problems in connection with the epilepsies, narcolepsies, the motor systems with particular reference to disorders of motility and muscle tone and their relations to Striatal disease. Certain instabilities of mood such as pathological laughing and crying are discussed and the various anatomical and physiological mechanisms underlying dysaesthesiae and the Argyll Robertson pupil.

With respect to epilepsy the author begins by noting the difficulty of giving even a good definition, and points out that while the fit is often spoken of as a disease it really *is nothing more than a symptom* correlation of which with the intrinsic processes of the nervous system is far from satisfactorily settled.

He does not regard the psychological explanation as sufficient. Even though underlying pathology cannot be demonstrated in all cases of fits he postulates a physiological basis. He has little use for the theory of regression in this connection. The origin of the stimulus is debated, particularly with respect to cortical and infracortical origins and cortical and transcortical decontrol. The uncertain relation of variations in cerebral circulation to muscular movements and unconsciousness is dwelt upon.

In considering the narcolepsies it is pointed out that any contrast between them and the epilepsies is simply contrasting symptoms and disregards the question of similarity of mechanisms behind each. It is concluded that up to the present our knowledge does not go far toward *a solution of the problem of mechanisms* responsible for the symptoms of this disorder, but the similarity of outward manifestations to those of the epilepsies is obvious and suggests the possibility of similar causes back of each.

In Chapter VI the author refers to "the old motor system and the new," and discusses it from the standpoint of comparative anatomy and physiology, experimental physiology, and clinico-anatomical studies and reaches the conclusion that disease of the cortico-spinal or new motor system "releases an action-pattern innate in the spinal cord." In this pattern there is increased tone and a maintenance of attitude. The outstanding clinical features of striatal disease are three—variability of muscle tone, involuntary movements, and absence of paralysis in the strict sense.

Under Disorders of Motility and Tone with reference to Striatal disease are discussed, voluntary motion, muscle tone, and involuntary motion. Parkinson's Disease and the Parkinsonian Syndrome are taken as examples *of a striatal malady. Various abnormalities falling in* each of the above groups have been observed and the conclusion reached that striatal disease per se does not directly explain the mechanism of their causation but that explanation must be sought elsewhere. "Notwithstanding weakness, slowness, rigidity and tremor, the ordinary muscular components of voluntary movement behave normally in cases of striatal disease, contrary to the views of not a few writers on the subject." In respect to involuntary movements, particularly choreoathetosis, he has this to say: "it represents a complex type of involuntary movement for the carrying out of *which motor mechanisms of cortical site* are requisite —it is the expression of disorder of a system. To its continuance afferent cerebello-cerebral defect of regulation contributes—any theory attributing its origin uniquely to striatal destructive lesions is impossible." As to tremor, "voluntary inhibition of this decontrolled mechanism is essentially imperfect, inconstant, uncertain and unsustained.—Tremor is an involuntary movement belonging to the old motor system (infracortical, subpallial), while choreo-athetosis *is an involuntary move*ment of the new (cortical and pallial) motor system." He voices his belief that the main features of striatal disease are muscle tone regulation disorder and appearance of involuntary movements. That they are "positive" symptoms caused by freeing of non-striatal mechanisms from striatal control.

Chapter XII refers to pathological laughing and crying and their frequent association with hemiplegia, pseudobulbar paralysis and disseminated sclerosis. Although attention is drawn to the obscurity of the mechanisms for these emotional states the suggested conclusion is that the emotional producing stimulus is cortically appreciated and "that there are corticifugal paths for the expression of the emotions via the facio-respiratory apparatus distinct from those of voluntary innervation of the same nuclei."

In studying the dysaesthesias with their neural correlates several clinical examples are given of the lesion at various levels. The conclusion is suggested that at times a neural at others a vascular or sympathico-vascular origin underlies the conscious manifestation of tactile painful, and thermal dysaesthesiae.

The Argyll Robertson pupil mechanisms are studied at some length. The author believes that the pupillary and visual paths to the superior colliculi are not identical and that the light reflex stimulus from the superior colliculi passes to the third nerve centres, in which, evidence seems to indicate is the pupillo constrictor centre from which the impulse passes through the ciliary ganglion to the sphincter iris. It would appear that distal to the third nucleus the pathways for iris contraction to light and convergence accommodation are identical.

Several theories as to location of the underlying pathology of the A.R. sign are mentioned, the most probable, he thinks being near the aqueduct, catching the fibres before they enter the third nerve nucleus. As to the myosis of many A.R. pupils there is also a good deal of speculation.

One is struck with the apparently unbiased logic of the author's approach to the solutions of these problems. It is a valuable contribution and should point the way to future successes in dealing with some of these vexing questions.

A. E. SOPER.

FOURTH OF JULY ACCIDENTS

The *New York Herald Tribune* of July 5 has a summary of the Fourth of July accidents occurring in New York City, which includes two killed and fifty-seven seriously hurt The list is as follows

Man, aged 29, killed by the bursting of a cannon of his own manufacture

Boy, 7, killed playing with fireworks

Man, 35, shot in hip by an unknown celebrator

Nine persons shot by blank cartridges

Man, 23, and man, 40, burned by firecrackers tossed on their arms

Boy, 15, burned by exploding blank cartridge which he was examining

Firecracker burns were the causes of injury of 13 persons, some of whom were holding the crackers in their hands and one was holding it in his mouth

Boy, 12, injured in the eye by a firecracker in his pocket lighted by another boy

Girl, 5, dress on fire from a sparkler

Three persons burned by clothing ignited from bonfires

Boy, 15, cut by a bursting bottle in which he exploded a firecracker

These are only the accidents which came to the notice of newspaper reporters in New York City within a few hours after the day of celebration Doubtless the newspapers will give a summary for the whole country within a fortnight

---

A COAT OF TAN

A sunburn is a certificate of a day's outing, a coat of tan is a diploma of a fortnight of leisure with the added halo of a martyrdom of sunburn to attain it The *New York Sun* of July 3 contains an editorial on how to tan gracefully, and quotes the following rules

"Acquire a coat of tan gradually, by repeated brief exposures to sunlight

"Do not sleep on the beach in the direct rays of the sun

"If your skin will not tan you are a 'heliophobe' and should avoid the direct rays of the sun

"When fishing or sailing do not forget that water reflects the ultra-violet rays of the sun

"In July and August protect yourself as much as possible from the direct rays of the sun if you want to avoid illness from sunburn"

The editorial proceeds

"This is sound advice at all times, it is particularly pertinent on the eve of the Fourth, when city dwellers go to countryside and beach. The sun's rays, if properly applied, have undoubted therapeutic value, but many recruits to the sun-tan treatment forget that overexposure may lead not only to pain but also to serious illness"

The soreness of the sunburn is evidence of skin injury and an inflammation in which there is an absorption of the dead products which produce sickness similar to that produced by a burn with fire If people understood the cause of the sickness, an inflamed skin would be considered as evidence of foolish recklessness It is well known that a sense of fatigue or general discomfort often follows even a mild degree of sunburn

---

TAKING THE PULSE

A mysterious halo has always been ascribed to the old doctor who with solemn dignity performed the ritual of taking the pulse An editorial written in the New York *Herald-Tribune* of July 8 says

"The bedside manner is threatened with losing its watch That first familiar act of the old-fashioned doctor, to take out his gilded turnip of a timepiece, touch your wrist gently and look both wise and comforting, turns out, science says, to be little better than medicine-man magic"

But after describing a new apparatus for recording the pulse beats, which he assumes that every doctor owns, the writer makes amends for his iconoclastic remarks by writing

"That traditional individual, the family physician, apparently doomed a few years ago to fade out into nothing in the shadow of the specialist, seems to be recovering his luster The facts about pulse counting are only one of the signs that knowing the patient whom he treats is one of the healer's greatest assets"

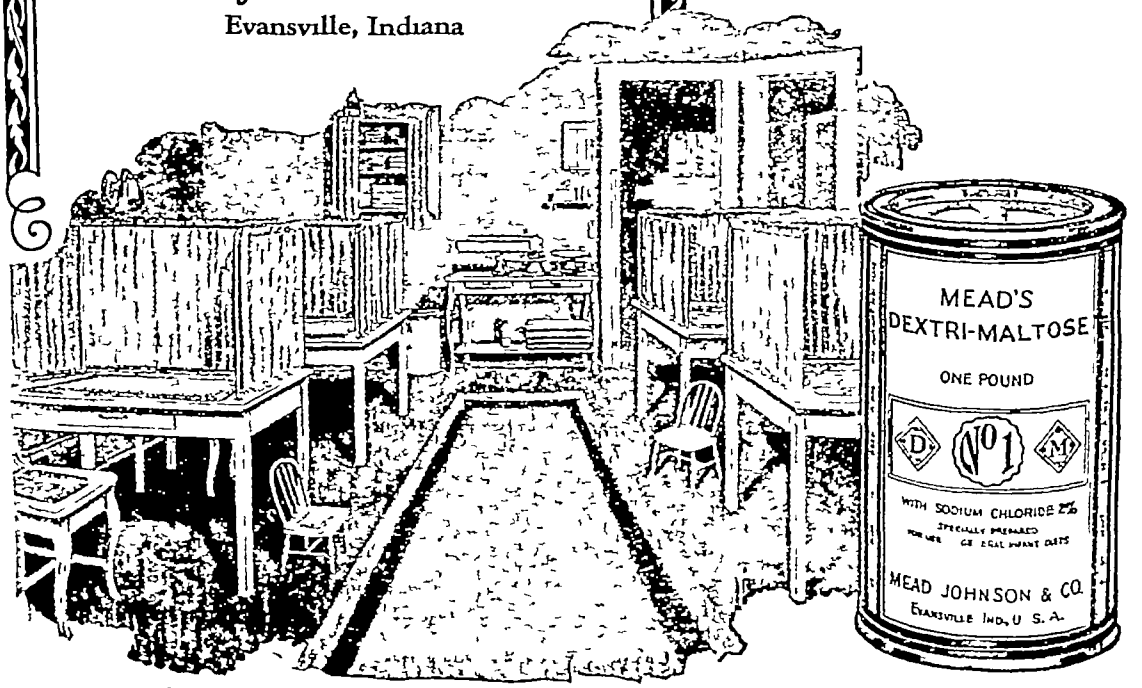
Mead's Dextri-Maltose

THERE is a unanimity of opinion among physicians upon the use of Mead's Dextri-Maltose

It is shared alike by the pediatrist whose practice is confined exclusively to the feeding of infants, and the general practitioner whose work covers a multitude of different cases

An abundance of clinical evidence has proved it is well tolerated, easily assimilated and generally productive of satisfactory results In combination with various cow s milk and water modifications it has probably *successfully* been used to feed more infants than any other carbohydrate offered the medical profession

A few infants can tolerate *any* carbohydrate But *any* carbohydrate can not be fed all babies under all conditions The success characterizing the use of Mead's Dextri-Maltose in the combined experience of infant feeders is that it will successfully feed *more* infants than any other now in use



Sample and Literature on Request

MEAD JOHNSON & CO.
Evansville, Indiana

MEAD'S

THE MEAD POLICY

MEAD S infant diet materials are advertised only to physicians No feeding directions accompany trade packages Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant Literature furnished only to physicians

OUR NEIGHBORS

KANSAS MEDICAL SOCIETY ANNUAL MEETING

Since the New York doctors held their annual meeting on June 3-6, they will be interested in the meetings of other state societies The Kansas physicians held theirs on May 7-9, at Salina, as reported in the June issue of the *Journal of the Kansas Medical Society,* which says

"The membership of the society remains practically the same year after year—around the 1,500 mark

"In 1925, according to the American Medical Association Directory, there were 2,364 physicians in Kansas, in 1927, according to this same authority, there were about 2,296 physicians in the state, a decrease of 68 in two years I might mention right here that the population of our state was increased by 59,000 during the same period of time I'll leave it to you to figure out how many additional patients each doctor is destined to attend"

Then follows five pages of reports from the ten councillor districts These review the condition of the county societies, and are excellent and informative to an unusual degree

Medical defense is discussed as follows

"The cases which we have had, during the last few years, have been, for the most part, better calculated to elicit a real fight in the courts It used to be the habit to bring suits against our members for the most unsubstantial reasons Lawyers were easily found who encouraged this practice, and doctors were also easily found who lent support to it But cases of this kind were often thrown out of court on demurrer or else were easily beaten in a short trial At the present time it is difficult to get a lawyer to undertake an action without strong prospect of success, from his point of view, and it is harder to get medical testimony to support a suit against a medical man The cases we do have therefore are harder fought, last longer and cost us more money than formerly It is still our policy to discourage compromise and to fight the cases brought against our members to the courts of last resort This has had the effect of deterring the litiginous tendencies formerly so prevalent

"It has cost the Defense Fund, as shown by vouchers from No 105 to No 120, inclusive, the sum of $2,297 43 to carry on during the past year This is $348 41 in excess of the expenses of the previous year"

"Defense Board Expenditures—15 Years"

1915	$ 1,254 95
1916	1,189 27
1917	777 45
1918	809 58
1919	759 41
1920	1,245 51
1921	1,458 35
1922	1,236 08
1923	1,310.96
1924	1,479 76
1925	1,970 05
1926	2,008 13
1927	1,981 03
1928	1,949 02
1929	2,297 43
Total, 15 yrs	$21,726 97
Average, per yr	1,448 46

Twenty-one cases were considered by the Medical Defense Committee, as follows

1 Fracture of femur Action lapsed
2 Puncture of bladder during child birth Action lapsed on the death of the doctor
3 Fracture of radius, pending
4 Appendectomy,—dismissed
5 Fracture of tibia Settled by insurance company
6 Injured tibia Jury disagreed at first trial Second trial, verdict set aside because of misconduct of a juror Third trial, jury disagreed
7 Fracture of radius,—failed to prosecute
8 Dislocation of elbow Two trials, verdict for the doctor
9 Fracture of radius, and no *x*-ray Verdict for the doctor
10 Fracture of radius Verdict for doctor, but is appealed
11 Burn from fluoroscope Verdict against the doctor who is appealing
12 Colle's fracture Dismissed
13 Gunshot wound, death from hemorrhage. Settled by insurance company
14 Mastoid operation Verdict for doctor
15 Sponge left in operation field Verdict of $1,000 against the doctor Paid by insurance company
16 Assault for performing an unauthorized operation Verdict for the doctor
17 Fractured forearm Doctor held
18 Failure to remove an instrument Settled by insurance company
19 Failure to attend patient. Doctor's demurrer to plaintiff's evidence sustained Motion for a new trial

(Continued on page 906—adv xii)

(*Continued from page 906—adv xii*)

"We were informed early and often that petitions were useless, that members of the legislature paid no attention to them—that they themselves so stated We happen to know, however, that the members of the legislature that passed the chiropractic bill gave the large petitions as their excuse for voting for it and the then governor gave the large petitions received as his excuse for not vetoing it. We have not yet been persuaded that there is an honorable legislator or rational politician that would ignore a petition signed by 150,000 voters, or 100,000, or even 50,000 voters

"From a summary of the activities of the members of the society in this campaign as compiled from the records in our office one can only conclude that fewer than 200 cared whether the basic science bill was passed or not

"Cooperation by the newspapers of the state is very essential in any educational campaign and particularly one of the character we have been trying to conduct. We feel that the Kansas newspapers have been very generous to us We are sending short articles to seventy of them every week

"Our publicity campaign can be most successfully conducted through the county newspapers, they reach a large proportion of those who need the education, but they can least afford to donate the space and can least afford to antagonize a considerable per cent of their paying patrons"

The report of the meeting closes with a discussion of the diphtheria campaign and the promotion of hygieia.

QUESTION AND ANSWER COLUMN

In the May first issue of this Journal, page 575, comment was made on the establishment of a "Question and Answer" column by Minnesota Medicine, the organ of the Minnesota State Medical Association The June issue of the Minnesota Journal has a page entitled "Consultation Bureau," in which question one and its answer read as follows

"What is the purpose of the Consultation Bureau?

"This service was established March 22, 1929, by the Committee on Hospitals and Medical Education Dr W A O'Brien, Assistant Professor of Pathology, University of Minnesota, was placed in charge A subcommittee was formed to assist Dr Meyerding and Dr O'Brien in working out the details of the plan Any member of the Minnesota State Medical Association may submit questions for answer and an attempt will be made to give an immediate reply If this is impossible, efforts will be made to make it as prompt as feasible, depending on the nature of the question Since

The Bureau of Public Relations reported as follows

"Since the Bureau of Public Relations was established, there have been prepared and sent out from this office 99,800 pieces of mail, pamphlets, reprints, circular letters, including 7,500 articles to newspapers in the state, and in addition a considerable amount of correspondence naturally required in the regular business of the Bureau

"Since May, 1927, the activities of the Bureau have been diverted somewhat from the original plan Its activities have been directed in large measure toward a publicity campaign for the basic science law More than 45,000 pamphlets, reprints and circulars concerning this proposed law have been mailed since that time in addition to several thousand letters"

The Bureau asked the cooperation of the 88 counties, and reported as follows

"Forty-eight of these men gave us more or less assistance and cooperation Some of these were very active and gave us very important and reliable information, but we are including among the forty-eight every one who replied in any manner to at least one letter

"But there were thirty-eight who did not even reply to a single letter, and if they took any part in the campaign our office received no information from them and has no record of any assistance from them"

"As the time for the convening of the legislature approached it seemed that some means must be found by which the people could express their wishes in the matter of legislation to the legislators Petitions seemed to be the only available means for this purpose We therefore sent blank petitions to each member of the society asking him to secure at least 100 signatures This would give us approximately 150,000 names and it did not seem probable that there might be a single member of the society unable to secure that many names Apparently we very greatly overestimated the popularity and influence of the members of our society in their various communities, or we were entirely mistaken as to the extent of their interest in the passage of this bill —for when the legislature convened we had received 8,274 names and these had been sent in by 129 members What shall one infer as to the other 1,370?

(*Continued on page 907—adv xiii*)

Matching the Blood Stream

IN a therapeutic substance it is not always practicable or even desirable to match the blood, because the blood stream is not only the food supply of the cells but also their outlet system for waste products.

Take a systemic alkalizer, for instance. It should contain neither sulphates nor lactates, as the former is a decomposition product and the other a fatigue product in the circulation.

ALKA-ZANE

furnishes potassium, sodium, calcium and magnesium in the form of *phosphates, carbonates* and *citrates*

For a practical understanding of its merits, let us send you a liberal quantity of Alka-Zane.

"5 An independent lesion

"Ringworm is said to be very common in calves, but veterinarians inform us that it is very unlikely that the patient has contracted ringworm from this source Favus is very rare in this country Anthrax must be considered but you did not describe the lesion Some type of fungus infection is very likely Perhaps the most important lesion to be considered is the independent affair Please send us a description of the lesion as this would be very helpful"

THE MAINE PUBLIC HEALTH ASSOCIATION

The medical profession of the State of Maine dominates all forms of public health work to an unusual degree through the Maine Public Health Association which is closely affiliated with the Maine Medical Association The Public Health Association, which was described in this JOURNAL of April 15, 1927, page 438, performs many of the functions which in New York are under the State Charities Aid Association

The entire June issue of the Journal of the Maine Medical Association is devoted to the annual reports of the Public Health Association The Field Secretary reports

"Incorporated as an 'educational institution' in 1920, the organization has grown steadily and consistently New departments have been added from time to time, and new activities have been made a part of our program Among our policies at present are listed the stressing of the annual physical examination by family physicians, the importance of early diagnosis, particularly for tuberculosis and cancer, a continuation of and increase in the public health nursing services, an emphasizing of the Clean-Mouth Campaign and Six-Point Child activity, an increase in our clinic program, a continuation of well-baby and preschool conferences and clinics, and last, but by no means least, the maintenance of the famous Maine Three-Quarter Century Club

"That the general public realizes the need and importance of public health work is shown by the fact that at the annual town meetings held during March, 1928, the sum of $14,655 00 was appropriated for the maintaining of nursing services under our supervision These appropriations varied from $5 00 to $1,800 00, according to the size of the town, the amount of work to be done, and the interest in public health nursing, but the total amount as compared to the $6,150 00 reported in 1927 is certainly encouraging"

The Public Health Association promoted a Three-Quarter Century Club, which is described as follows

SAFE, SIMPLE INFANT FEEDING

HORLICK'S MALTED MILK is safe and simple in infant feeding Its successful use for nearly half a century has demonstrated the following outstanding advantages

1 The readily assimilable state of its minerals promotes sound bone and tooth structure

2 The light, flaky curds produced because of the modified nature of its milk constituent aid digestion.

3 The exact proportions of its malt sugars promote regular bowel action in the infant.

4 The exclusive Horlick process conserves the vitamin content of milk and malted grains unimpaired.

For samples address—HORLICK, Racine, Wis

the opening of the Bureau, the following types of questions have been received

"1 Difficult diagnostic problems
"2 Inquiries concerning new drugs
"3 Medical legal questions
"4 Information concerning good textbooks
"5 Opportunities in graduate study

"One of the interesting features has been a large number of diagnostic problems submitted Every one is requested to use the Bureau as much as possible and any member of the State Medical Association may be called on to help out in answering the questions This is just another example of the trend in medical practice of working together for self-betterment and for better service to our patients"

Question number 2 is on whooping cough, and number 3 is on pulmonary hemorrhages

Question number 4 and its answer are as follows

"Female, age 45, complains of a swelling in the deltoid region, which has been coming on gradually for the past two years There has been more rapid growth in the last three months Patient complains of pain in the shoulder and arm at times She fell down the stairs about eight years ago, striking this shoulder It became black and blue, and she was unable to use the arm for some time Since then, she has had rheumatism in this region Tumor is the size and shape of half of a small orange and is not tender When the arm is passive, the tumor is soft, but when the muscles are contracted, the mass becomes hard and elevated Radiographic examination shows a tumor of the soft parts There is apparently no involvement of the bone The tumor is apparently partially calcified.

"Answer The most probable diagnosis is encapsulated hematoma Because of the difficulty in being absolutely certain, it is advisable to do a biopsy It may be necessary to excise the mass, even if it is found to be benign, because of the pain"

Question 5 is asked and answered as follows

"I have a patient who has what he calls 'calf-itch' His calves have some sort of an itch, and he seems to have contracted it What is the post probable diagnosis, and what is the treatment?

'The following conditions should be considered

'1 Ringworm
"2 Fungus infection
"3 Favus
"4 Anthrax

(*Continued on page 909—adv xv*)

(*Continued from page 910—adv xvi*)

ticians who have given this valuable service largely for the benefit of the rural sections of this state who are greatly in need of such a service All the expenses of these clinics are borne by the Maine Public Health Association The nurses have given valuable assistance in the Early Diagnosis campaign Through their initiative, thousands of little booklets, 'Let Your Doctor Decide,' have found their way into pay envelopes of the industrial plants in the state The health films, Let Your Doctor Decide,' also has been shown before many audiences, and large posters in store windows and schoolrooms show that the public health nurses are ever thinking how they can best teach health in its broadest and most constructive sense to their people. The nurses have this year helped to provide reparative clinics in dentistry in three new territories for children who are unable to pay only a small sum By teaching the little ones the way to the dentist's office early in life, perhaps they will have acquired the habit so firmly that they will continue to go in adult life."

The latter half of the Journal contains the reports of the branches in the several counties of the State

BALLOTING BY MAIL IN COUNTY SOCIETIES

"The Philadelphia County Medical Society has adopted the plan of voting by mail How the plan works is told in the following editorial in the Pennsylvania Medical Journal for June

"The membership of this county society averages about 2,200 It is never possible to obtain a representative vote at the annual meetings or when conduct of business by ballot is necessary Owing to the facts that the meetings are held in the evening and to the extent of territory covered by Philadelphia County (the city and county being the same), it is exceedingly difficult for general practitioners who have evening office hours, more especially those living a distance from the place of meetings (who sometimes have to traverse fifteen miles) to reach the place of meetings in time to hear a greater portion of the scientific programs or attend the business sessions

"In order to obtain a representative vote, it was deemed advisable, in considering a revision of the by-laws, to make it valid to vote

Committee on Publication

(*Continued from page 909—adv xv*)

"Perhaps the most unique phase of our program is the organization and continuation of the famous Three-Quarter Century Club Many state associations give particular care and attention to the boys and girls in their commonwealth, but, so far as we can ascertain, the Maine Public Health Association is the only state organization that duly recognizes with honor and festivities the residents who have achieved longevity In 1928 the annual field day and reunion was held in Bangor, August 2nd, and the Chamber of Commerce of that city entertained the group, numbering about 5,500, in royal manner"

Finances are described as follows

"In summing up the year's finances very briefly, a total of $64,004 53 was received, while the expenditures were $62,618 86 leaving a balance Jan 1st, 1929, of $1,385 67 in the treasury All bills have been paid, and the Maine Public Health Association begins the new year with all debts eliminated, and expressing the hope that the wonderful spirit of cooperation which has been so evident during the past year will continue through 1929'

The report of the Health Education Service is devoted principally to activities of the Modern Health Crusade and the Clean-Mouth Campaign The Six-Point Child activity which was described in the New York State Journal of Medicine is briefly described and a seventh point was added based on the registration of the child's birth The report of the Director of the Nursing Staff also refers to the six-point child as follows

"No nurse is meeting completely the needs of her service unless she stresses health education The minimum health requirement, the Six-Point Child, for the school pupils and children entering school, was adopted and sponsored by this health association in the latter part of the year No project was ever received with greater enthusiasm or with more success Over 5,000 school children had qualified at the end of the year on the six points of health, namely, teeth, throat, vision, hearing, posture and weight It had become a great factor in securing corections of defects The children insist on being 'Six-Pointers' and therefore the parents must have the necessary corrections done"

The Clinic service is described as follows

"Reorganization of the state-wide clinic program is being started this year A full-time clinic nurse has been employed for six months She will be sent in any territory which desires a diagnostic clinic in lung, heart, cancer or orthopedic conditions, and will look after the details in the carrying out of such a clinic, also consequent follow-up This nurse will work in cooperation on this clinic program with a staff of diagnos-

(*Continued on page 911—adv xvii*)

MEDICAL SPEAKERS

The Journal of the Kansas Medical Society for June has the following editorial remarks about medical speakers at the State meeting

"In order that the three-hundred-fifty who did attend the meeting might be able to discuss these papers intelligently it would have been a good idea to have the secretary or some one with a good voice, read them for the authors Why would it not be a good plan to appoint a reader at each annual meeting, just for the purpose of reading for those who fail to make themselves heard?

"Occasionally there is one who can put on an illustrated medical lecture successfully, but they are few and far between In the first place lantern pictures require a good deal of explanation to be worth while and twenty minutes is not long enough to describe more than a few pictures in connection with a paper Charts which appear to be coming into fashion again are usually unintelligible when thrown on the screen, most of them being so prepared that the projected image cannot be read by a majority of the audience. A few years ago there was a fad for graphs and every lecture and published paper was accompanied by from one to twenty or more They are rarely seen now, but charts and projected pictures were much in evidence at the Salina meeting A few good pictures which really illustrate some particular point in the text of the paper may be worth while, but the majority of those usually shown don't tell the audience as much as would one or two carefully formulated sentences made up of carefully selected plain understandable English words

"There are occasions when a lot of time is consumed entirely foreign to the question before the house, or about various things when there is no question before the house but that is the fault of the presiding officer Parliamentary rules were formulated for the purpose of expediting the proceedings of such bodies as our House of Delegates and lack of observance of these rules is responsible for a great deal of wasted time And yet it seems that our delegates resent any attempt to enforce observance of these rules either by the presiding officer or other members of the house. Even when the presiding officer is experienced in parliamentary usage he hesitates to enforce the rules in face of the obvious displeasure of the members"

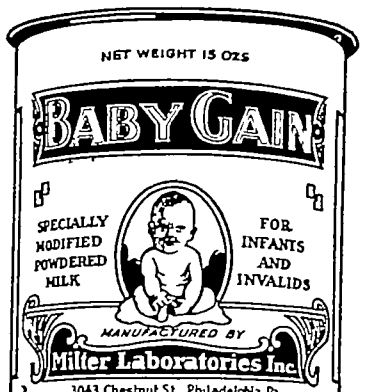
by mail Announcement was duly made to the members that a special business meeting would be held April 24th, at 10 p m, following the scientific meeting It was announced that the meeting was 'to vote upon the proposed changes in the by-laws as published in the *Weekly Poster*, granting permission of all members of the society to cast votes by mail' There are other changes in the by-laws to be acted upon at the same time



"It is of interest to note that only 242 votes were cast The change in the by-laws permitting balloting by mail was approved by the very narrow margin of five votes The argument of the opponents was that if a member had the interest in the county society he should have, he would be willing to sacrifice his office hours or any other engagement to attend a business meeting It was demonstrated at the meeting that casting a ballot by mail will be as secret as casting it in person at a meeting

"The Board of Directors requested the counsel for the society to submit for their consideration a resolution which would make balloting for officers and revision of by-laws by mail obligatory, no balloting to be done at the time of the business meeting This resolution was duly adopted, and the instructions for balloting given the required publicity

"At the annual meeting held May 15th, with a membership of 2,200, there were 903 ballots cast—the first in the memory of any of the living members that anything approximating a representative vote had occurred In the instructions, attention was called to the fact that the ballots must be received in the mail at the designated place not later than noon of the day of the meeting Only three ballots were received after the prescribed time, and of course were not opened One physician delivered his ballot, after the time, at the wrong place There were two candidates for president, the winner, receiving 450 votes, his opponent 442 votes

"The chairman in charge of the tellers, was especially selected because he was unalterably opposed to balloting by mail, with the thought of reassuring the opponents as to the fairness of the procedure

"It is conceded by the majority of the members that balloting by mail is very desirable."

Pure Milk from
Tuberculin-Tested Cows
Modified and Powdered

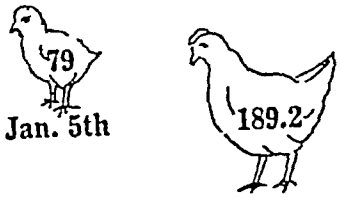
Infants Thrive on BabyGain

The physician may safely prescribe BABYGAIN in cases where he deems it advisable to discontinue or complement breast feeding

BABYGAIN is more easily digested than modified fresh cow's milk, due to the reduction in the size of the butterfat globules and the breaking up of the casein flocules in our process of dehydration

BABYGAIN, restored to liquid form, agrees with the standard average analysis of mother's milk and its physical characteristics Feedings may be regulated to meet individual requirements

The use of BabyGain will help to prevent summer diarrhea



MILTER LABORATORIES, Inc.
3043 Chestnut Street, Philadelphia, Pa.

Please send me free sample can of BABYGAIN and descriptive literature

COUNCIL ON PHYSICAL THERAPY DEMONSTRATES BIOLOGICAL VALUE OF WINTER SUNLIGHT THROUGH VITA GLASS

A reprint in abridged pamphlet form is now available, presenting details of a test by the Council on Physical Therapy of the American Medical Association, to determine the biological value of winter sunlight as transmitted by different types of window glass This experiment was fully reported in the Journal of the American Medical Association for May 14, 1927

Chickens were fed a diet deficient in Vitamin D Results The Vita glass chickens gained more than twice as much weight as the control group (under common glass) and were free from all clinical signs of rickets, (although two chicks out of the 14 showed slight traces of the stigmata of rickets under X-ray examination,) while all the control group developed rickets

The results from the Vita glass group and the mercury vapor arc group, as regards gain in weight and immunity from rickets, were practically identical

In summarizing its conclusions from this experiment, the Council reported in part "The results of these investigations encourage the belief that there are now available materials for glazing our windows which do not possess the fault of window glass in excluding the health-giving rays of sunlight"

The Council's demonstration of the antirachitic efficiency of winter sunlight through Vita glass is substantiated by the results of similar tests conducted with white rats by Captain William D Fleming of the U S Army Medical Corps, and reported in recent issues of the *Military Surgeon*

Reprints of Captain Fleming's reports are also available, and may be secured, together with the digest of the Council's experiment, by mailing the accompanying coupon

Vita Glass Transmission Constant After Few Weeks Exposure

Vita glass has been subjected to numerous accelerated weathering tests by the U S Bureau of Standards, by Professor Stockbarger of the Massachusetts Institute of Technology, and by many other physicists. These physical or quantitative tests, as well as biological experiments with rats and chickens, have established the fact that the solarization (weathering or seasoning) of Vita glass takes place quickly and that after a few weeks of actual use its transmission of ultra violet light becomes constant

Vita glass is being marketed primarily as a health prophylaxis, and not as a therapeutic agent, although it is now serving in the latter capacity in numerous well authenticated instances—particularly in the solaria of more than 200 hospitals in England and the United States.

VITA GLASS

IGNORANCE REFLECTED IN MEDICAL LEGISLATION

The June issue of the Michigan State Medical Society has the following editorial discussions of the need of educating the legislators

"There exists a misunderstanding in the minds of many legislators in regard to the whole matter of the healing art Someone probably has felt himself unfairly dealt with by some member of the medical profession, henceforth he has a grudge against the whole profession This shows a poor faculty for generalization It is as if a person who fell downstairs should move for the abolition of this mode of seeking a higher or a lower level The members of the medical profession are human, they do not claim to be any better nor any worse as individuals than the members of any other profession or social group They have sought to improve their profession as such and to advance medical knowledge by encouraging and where possible participating in medical research They have hitherto given freely of their time to indigent sufferers as well as in aiding in the great field of preventive medicine They do not ask anything for themselves, but they are extremely solicitous of the future of the art and science of medicine, anxious, because they are in a position to realize the medical situation as no one else can be expected to realize it

"The admission of the healing cults to rights and privileges (and also may we add responsibilities) of medical practice is tantamount to admitting a layman who has a smattering of business law to the right to practice every branch of law, or a person who has acted as an architect's building inspector to practice architecture on the same terms as a master, or the person with not even a smattering of the science of engineering to engage in the erection of some gigantic structure

"If the attitude of a considerable portion of the legislature can be said to reflect the opinion of the state regarding scientific medicine, there is a big field for health education as it has been carried on by the Joint Committee on Health Education However, with the ample facilities for medical training which the people of Michigan have provided at the state university it is difficult to realize that they would endorse the legislative acts of some of their representatives"

PRECEPTORSHIP FOR MEDICAL STUDENTS

The *Wisconsin Medical Journal* for June discusses the probable influence of medical preceptorship on the distribution of physicians to rural districts and says:

"Merging of the theoretical into the practical is the problem of medical education today. To distribute medical service equitably among those who need it is a proposition in which both physicians and laymen are interested.

'How far physicians are losing the missionary spirit in the struggle that is forced upon them by high standards and a long and expensive course of training cannot, as yet, be estimated. Whether the commercial is supplanting the missionary spirit may be debatable but the fact remains that intensive technical instruction is diverting the present day graduates from rural locations to the larger medical centers where there are better facilities for cultural development, contact with leaders and where prospects for financial gain are more alluring

"It is a truth that no one will question that doctors cannot be too well prepared for the responsibilities of medical practice but it is a question whether or not modern methods of education are producing the highest grade of practitioners for the all around requirements of the people they will be called upon to serve.

"The medical graduate, unless he be among those fortunate enough to secure a position in a clinic or association with someone with an established practice, must readjust himself to the needs of the people or communities he offers to serve. And his big problem during the first few years of practice is so to adjust himself and so apply the knowledge he has acquired as to establish himself in his chosen location, and give the service expected of him

"The University of Wisconsin, by its preceptorial plan, has taken a long step ahead in medical education. The three months the senior student spends with a preceptor, and his group brings him into closer contact with actual conditions of practice than an internship possibly can.

"If he takes advantage of the opportunities offered, he sees the emergencies and learns to meet them. He sees patients in their homes and under all kinds of conditions from poverty to wealth. He learns something of the problems of the home as they come under the observation of the physician and sees the many sides of the treatment of the sick in body and mind.

'He acquires a degree of tolerance for the weakness of humanity and a broad conception of his mission and learns that his is a profession and not a business. He learns the many sides to a doctor's life while ministering to the varied needs of suffering humanity, and finds that there is compensation for his service that cannot be measured by money though faithful and efficient service will bring adequate financial returns.

'He is given a glimpse of the difficulties of reaching patients in remote sections giving service in the presence of most adverse conditions and a realization of the joys of accomplishment

The student with a receptive mind cannot help being greatly benefited by his experience during his period with a preceptorial group, and the experiment of our university give promise that it will be adopted generally as an essential in every medical college curriculum. How far it will go toward solving the problem of adequate service to the rural communities remains to be seen but it is certainly a step in the right direction."

If pure water is important to people in good health, how much more essential it is to invalids.

EDUCATIONAL ADVERTISING

Why don't physicians turn eagerly to advertising pages of Medical Journals? Manufacturers and dealers pay considerable sums money to writers for planning advertisements that make a compelling appeal to the eyes a minds of physicians who constitute a most telligent group of educated persons Yet t fact remains that the great run of medi advertisements have but little appeal to dc tors Either their science is not of the popul brand, or the literary form is dry and obscu Yet some firms are striving to write advertis ments which will compete with the scientii articles in giving the doctor pleasure a profit Such an advertisement is that whi appears on advertising page 16 of the July 6 issue of the *Journal of the American Medic Association* and which reads as follows

"Few people think of candy as a food Fc most it is an indulgence with few positive vi tues beyond its power to please the palate has been accused of injuring the teeth, harder ing the arteries, upsetting the digestion, caus ing rheumatism, cancer, diabetes

"From the standpoint of nutrition, candy i a food, particularly valuable as a source o quick energy The problem of dietitians is t get people to eat it rationally, as part of balanced diet

"To correct popular misconceptions and t make available to the layman modern scientifi thought on candy as a food, we, the Nationa Confectioners' Association, are carrying on campaign In this work we are guided by competent technical counsel

"We believe such advertising is a public service We welcome suggestions and criticisms of our work from those professionally interested in public health We have taken into account the many letters we have already received"

We will be interested to see how successful the Confectioners' Association will be in inducing people to, eat sugar rationally This will include samples of balanced diets including candy for desserts on an equality with ice cream and pie Folks can use candy just as well as they do any other form of dessert, but doctors will question the ethics of switching people from cake and pudding to candy

From a point of view of scientific dietetics, only a certain amount of sugar is allowable, and if it is taken in the form of candy, less ice cream must be eaten

After all, doctors are not chiefly concerned over the relative prosperity of ice cream manufacturers and confectioners — they are concerned with spreading the truth regarding the food value of candy

TUBERCULOSIS AND ASTHMA IN CHILDREN*

The Incidence of Positive Tuberculin Tests in Children with Asthma and Their Relationship

By HENRY A. REISMAN, M D, JAMAICA, N Y, and RAOUL L MASON, M D, NEW YORK, N Y

From the Pediatric Department of the New York Post Graduate Medical School and Hospital

THE solution of an asthmatic condition in children is at times both baffling and discouraging It frequently taxes one's ingenuity We are beginning to realize more every day that asthma is a symptom the causative factor of which presents a problem in diagnosis, that sometimes defies solution Heretofore, up until about one year ago, much attention was given to the extrinsic causes such as inhalations (Pollens and Emanations) and ingestion (foods) The intrinsic causes such as infections of the lungs, foreign bodies and foci of infection outside the lung, as sinusitis, are now coming to the front as playing an important role in the causation of asthma. Stout[1] reports sinusitis in 26% of a series of cases of bronchial asthma. The result of the treatment of the sinusitis upon the asthmatic condition has definitely proved more than a coincidental relationship Manges and Hawley[2] found that of 155 children, who had foreign bodies in the air passages, six at one time had been diagnosed as asthma. For the past several years we have studied the asthma patient from the standpoint of Tuberculosis and two years ago began routine tuberculin tests (intra-dermal) on all asthmatic children, the results of which we found most interesting

The intra-dermal tuberculin test (1-1000) was performed on all children in the Asthma Clinic, the ages varying from 8 months to 14 years In some instances where the test was negative the mantoux was repeated with a more concentrated solution (1-100) The tests were read at the end of 48 hours and a week by a disinterested third party Of 158 consecutive cases of asthma in the Asthma Clinic 61 (38 6%) gave a positive tuberculin test. This is an unusually high incidence of tuberculous infection particularly in our age group and it does not include several definite cases of tuberculosis where the patient did not return for the reading of the test and where the tuberculin test was negative because of previous tuberculin therapy, for tuberculin therapy is one of the causes of a negative tuberculin test in the presence of a tuberculous focus

The question arises therefore as to how we are to interpret the above results There are just three possibilities

(1) That asthma and tuberculosis occur independently of each other and that there is no relationship

(2) That asthmatic children are particularly susceptible to tuberculosis

(3) That many tuberculous patients present symptoms of asthma

That there is a relationship is evidenced by the fact that 38 6% of the children (8 months—14 years of age) presenting asthmatic symptoms gave a positive tuberculin test compared to 16 9% (5 yrs —14 yrs) of the non-asthmatic children There is therefore an excess of over 21% If there was no relationship whatsoever one would expect to find about the same percentage of positive tuberculin tests among the asthmatic as in the non-asthmatic child Surely one would not expect to find a greater percentage, no more so than we would expect to find a greater percentage of positive tuberculin tests among those with ingrown toe-nails At least the increase should not be so overwhelming Chadwick[24] performed tuberculin tests on grade school children selected because they were either underweight, in poor health or because they gave a history of contact Of about 30,000 children thus tested he obtained a positive tuberculin test in only 2,806 children (9 3%)

As for the second possibility it is obvious that in order to give a positive tuberculin test one must come in contact with a tuberculous individual or material and hence become infected, although in many instances a history of contact may not be elicited Being susceptible has nothing to do with the child coming in contact with the organism although it may have something to do with the

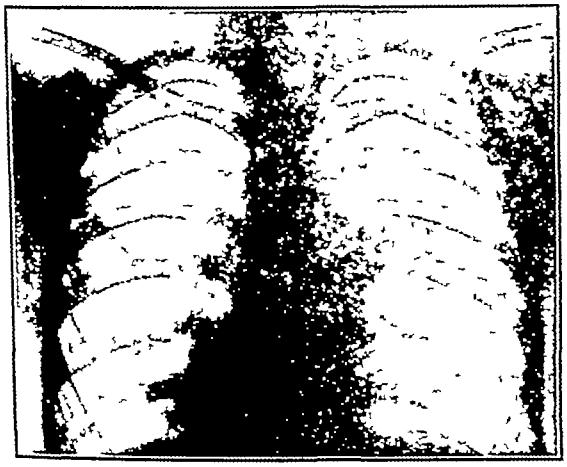
Dear Doctor:

Have you considered the advantages offered by membership in the "MUTUAL?"



A small investment, no C. O. D. or Cash with Order payments, an Annual Dividend and participation in all Profits.

MUTUAL PHARMACAL CO., Inc.

(2) R. H, male, age 12, had frequent attacks of asthma and gave a positive tuberculin test On physical examination we found a positive D'Espine sign, and crepitant rales in the right upper lobe anteriorly indicative of the beginning adult type of tuberculosis Mother has definite evidence of tuberculosis and his sister seven years of age, has a positive tuberculin test with a moderate Hilum glandular enlargement

Case 2—R. H, Roentgen Ray Examination, *X*-ray Interpretation

Examination shows sufficient mottling and nodulation at the hilus to suggest an old tuberculous lymphatic infiltrative process This responsible for further root branch thickening In addition to this, the upper intercostal branches are accentuated, visible in the first and second intercostals on both sides, somewhat more prominent on the right, suggesting the likelihood of a

CASE 3

congestive stage of infiltration in the parenchyma, especially in the right upper lobe

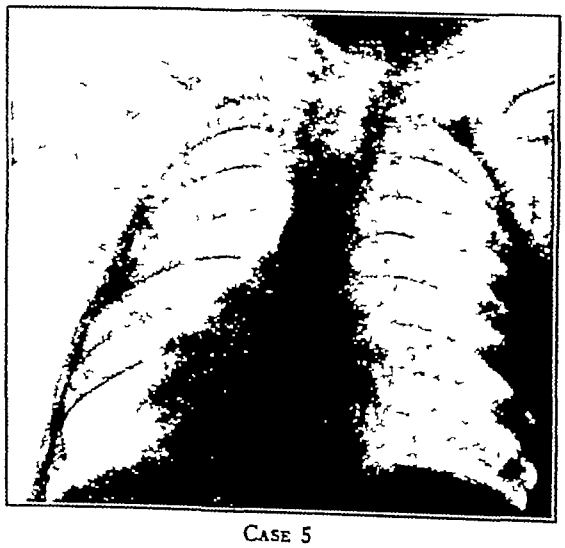
Diagnosis Old lymphatic hilus tuberculosis

(3) V H, female, age 7, continuous attacks of asthma Behind the asthmatic wheezing which was present throughout the whole chest, showers of fine crepitant rales could be heard, posteriously on both sides near the spine, at about the level of the angle of the scapula, typical of the active juvenile type of tuberculosis The whole family is suspected of being tuberculous Patient is at present in a tuberculosis sanatorium

Case 3—V H, Roentgen Ray Examination, *X*-ray Interpretations

Examinations show the heart proportionately quite small A very pronounced infiltrative process is seen extending from the hilus into the central lung field, not so much along the root branches as towards the interlobar septal region, especially so on the right side The likelihood is

CASE 4



that an actively progressing lymphatic hilus tuberculosis

Diagnosis Actively progressing lymphatic hilus tuberculosis infiltration

(4) M B, female, age 5 years Frequent asthmatic attacks which continued for 6—8 weeks Has positive Tuberculin test Physical signs revealed fine crepitant rales in 3rd interspace anteriorly near sternum with sibilant and subcrepitant rales thruout chest She has a positive tuberculin test and clinically she is tuberculous

Case 4—M B, Roentgen Ray Examination, *X*-ray Interpretation

Examination shows the total heart area proportionately small The hilus is the seat of an old lymphatic infiltrative process with fibro-calcific nodules, this infiltration has extended along the lower root branches with a partial central consolidation of the left lower lobe. The appearance is that of a hilus tuberculosis with probable

CASE 5

activity of the disease after infection has taken place It is the contact with subsequent infection that will produce a positive tuberculin test and there is no reason to believe that asthmatic children have a priority in becoming contacts or infected

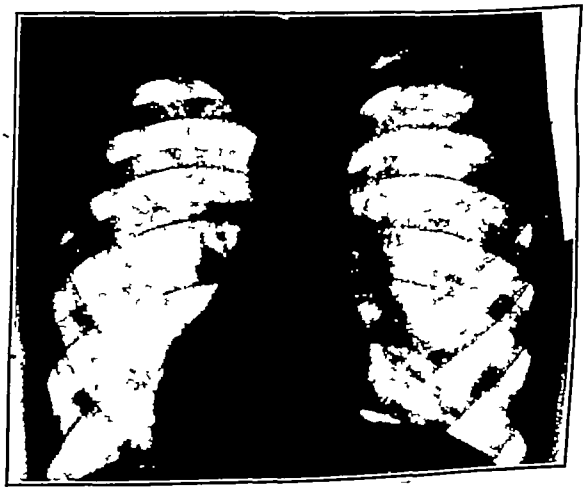
It seems to us, therefore, both by exclusion and inclusion that all evidence points to the third possibility, that tuberculous patients present asthmatic symptoms This is substantiated by both the high incidence of tuberculous infection and our clinical data, namely, history of contact, physical signs, *x*-ray findings and tuberculin therapy

Charles Hendee Smith[5] in a large series obtained a positive tuberculin test in 16 9% of children between the ages of 5-14 years and living in our locality Using this as a standard (for many have reported a lesser incidence, (Sill[6] 9 2%, Slater[4] 5 3% and 8 6%, Chadwick[24] 9 3%) and comparing it with the figure obtained from our asthmatic children 38 6% we find an excess of over 21% positive tuberculin tests in children presenting symptoms of asthma It is logical to assume that that excess 21 7% is due to the role that tuberculosis plays in children with asthma Similarly we would expect to find a higher incidence of tuberculin tests in children with large chronic cervical adenitis, because the percentage and role that tuberculosis plays in chronic cervical adenitis would be superimposed upon the incidence of tuberculous infection in the average child

We do not wish to convey the impression that over 20% of all asthmatic children are tuberculous in origin In our group we found many who were definitely tuberculous Naturally the part that tuberculosis plays in asthma will vary with the group Our problem of absolutely proving a relationship is difficult because the diagnosis of tuberculosis is lacking in precision and because of the difficulty of proving the tuberculous focus to be the cause of the asthma Our results may seem at first an exaggeration but a review of the clinical history of a few of our cases not only corroborates but still further emphasizes the opinion that in a large percentage of cases the asthma is due to a tuberculous focus Grossfield concluded after investigating 215 cases of Bronchial asthma, that most true cases of asthma are of tuberculous origin This view we believe is the other extreme

(1) E S, female, age 13 years, had almost daily attacks of asthma and gave a positive tuberculin test Physical examination revealed a positive D'Espine sign, moist and crepitant rales posteriorly near the spine at the level of the angle of the Scapula with some crepitant rales in the apices Throughout the chest there was typical asthmatic breathing, clinically she was tuberculous For a long time we were unable to elicit

CASE 1



a history of contact. About three months ago we learned from Mrs S that the father had then died of pulmonary tuberculosis

Case 1—E S, Roentgen Ray Examination, *X*-ray Interpretation

Examination shows the condition practically as previously reported, namely the heart is of the elongated, dropped type yet with pronounced bulging of the left auriculo-pulmonic curve along with aortic retraction The heart picture is that of a mitral stenosis

The pronounced hilus, root branch and central bronchial thickening is also as previously noted, with a nodulation in the central lung field suggesting tubercle the probable etiological factor

Diagnosis Mitral stenosis Hilus T B

CASE 2

(3) Harsh breathing
(4) Abdominal distension

History About two months ago baby developed a cold and breathing became harsh A diagnosis of bronchial asthma was made by a prominent Pediatrician One month later child developed fever and cough The breathing still remained harsh Since then temperature has varied from 99—104° and not associated with any particular time of day

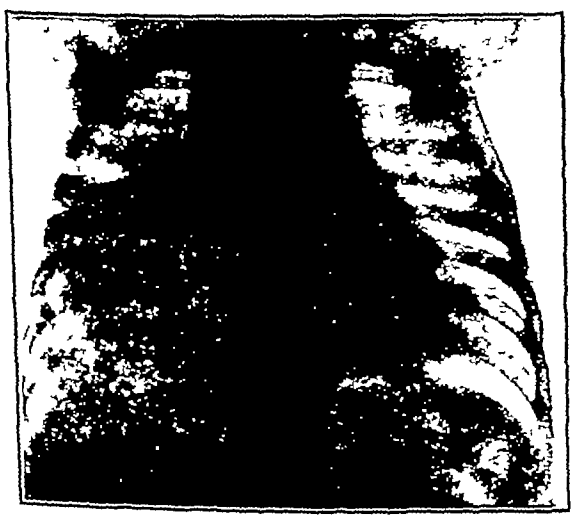
Physical Findings

(1) Impaired resonance right side posteriorly particularly over middle and lower lobes with diminished breath sounds

(2) Sonorous and sibilant rales throughout chest both sides together with some fine crepitant rales

Diagnosis on Admission

(1) Thickened Pleura
(2) T B Central Pneumonia, right
(3) Foreign body



Temperature 103-2 on admission with irregular fluctuations between 100 and 105

Laboratory findings

(1) Mantoux 1—1000 positive
(2) Blood count

R. B C	4,	176, 000
W B C		16, 000
Poly,		78%
S L		18%
L L		3%
Trans		1%

(3) Urine negative
(4) *X*-Ray See illustration H C L
Died April 7, 1927

CASE 8

Autopsy Summary

(1) Caseous pneumonia and tuberculosis bronchitis and peribronchitis of left lung
(2) Broncho-pneumonia right lung
(3) Tuberculosis ulcerations of intestines
(4) Tuberculosis of lymph glands, pulmonary and mesenteric
(5) Miliary T B in spleen, liver and pancreas
(6) Tuberculosis Pleuritis

Here again we have histories of contact of sanatorium care with the physical findings confirmed by autopsy as in H C L with *x*-ray findings and positive tuberculin tests which form corroborative links in the diagnosis of tuberculosis

Case 8—H C L., Roentgen Ray Examination, *x*-ray Interpretation

Examination of the thorax shows almost absent illumination of the lower two-thirds of the right pulmonic field. This area is bounded superiorly by the interlobar septum, and since the density is seen centrally with a convex line of demarcation, suggests the likelihood of an encapsulated exudate though the possibility of a central lung abscess must also be considered

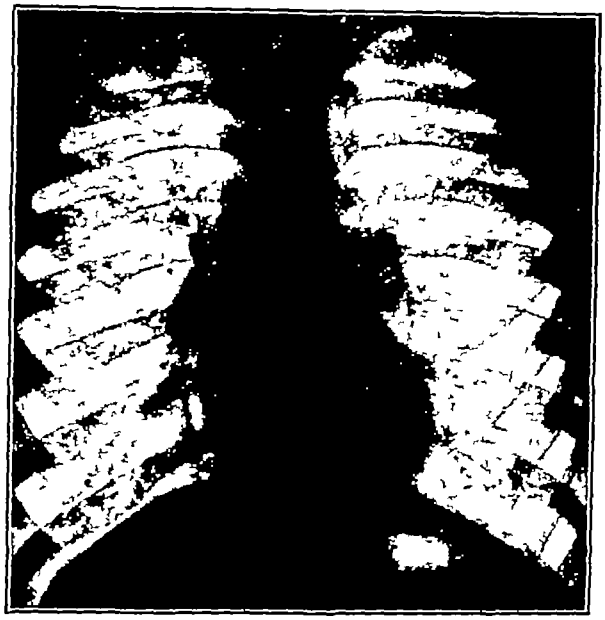
In addition to this, there is a central bronchial pneumonia in the visible portion of the right upper lobe

Diagnosis Central bronchial pneumonia, concomitant pleuritic involvement, probable abscess at right base, interlobar as well as lung involvement to be considered.

Contrary to the teachings of the last decade that there was an antagonistic action between asthma and tuberculosis we now find them very closely related Variot and Bruder[8] in 1904 were the first to observe the expiratory type of dyspnea associated with enlarged Tracheo-bronchial glands In 1907 Bougaral[9] reported ten cases which he collected from the literature Schick[10] in 1910 presented 36 cases of asthma caused by Tuberculous Tracheo-Bronchial glands of which 13 were confirmed by autopsy He maintained that in infancy and early childhood the occurrence of expiratory dyspnea and wheezing were diagnostically significant of Tuberculous Hilum glandular enlargement A positive Tuberculin reaction and Roentgen Ray findings corroborated the diagnosis Eckert[10] Rach[11] Sauer[12] Hall[13] Fishberg[14] Pierson[15] Finkelstein[16] Ratner[17] Marfan[18] and Abt[19] have reported cases of Tuberculosis of the hilum glands in children simulating asthma Peshkin and Fineman[20] reported three cases out of several hundred under observation

Throughout the literature the opinion is almost unanimous that the asthma is due to some form of pressure or obstruction from the enlarged tracheo-bronchial glands Schick[13] stated that the pressure is exerted at the bifurcation of the trachea or main bronchus Cameron[22] Eckert[11]

tuberculous pneumonia extending along the lower root branches, especially prominent in the central-lower lobe



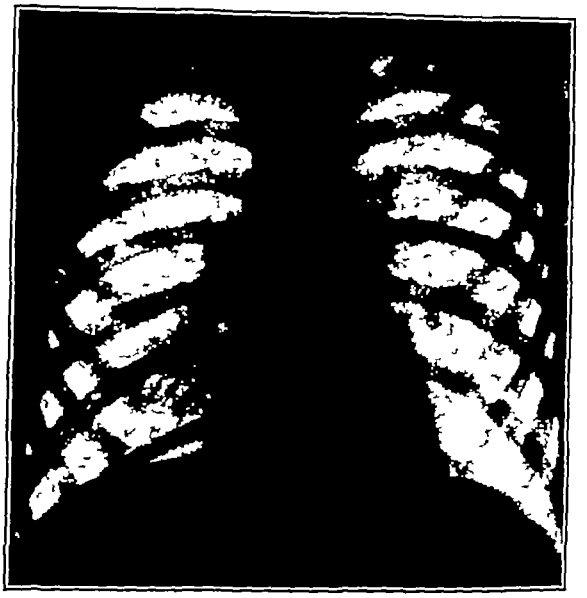
Diagnosis Hilus tuberculosis Central tuberculous pneumonia

(5) K A, male, age 3½ years X-Ray shows central tuberculosis Has positive tuberculin test Had attacks of asthma at least every month Has not had an attack since Mantoux and tuberculin therapy

Case 5 K A, Roentgen Ray Examination, x-ray Interpretation

Examination of the thorax shows considerable lymphoid nodulation at the hilus and in the central lung field suggesting the likelihood of hilus and central tubercle infiltration

It may be worthy of note that the fifth rib on



CASE 6

the left side is congenitally small and apparently without attachment at the costo-condylar junction

Diagnosis Hilus and Central T B

(6) M K, male, age 13 years Frequent attacks of asthma since 3 years of age Mother died of tuberculosis 8 years ago Crepitant and subcrepitant rales were heard near spine at about level of angle of scapula *X*-ray revealed typical juvenile tuberculosis Tuberculin therapy with a 1-1,000,000 dilution prevented further asthmatic attacks Through an error he was given stronger solution of tuberculin 1-100,000 and he had an attack of asthma all week The patient was forewarned that this would occur, further injections with the 1-1,000,000 dilution again kept him free from attacks

CASE 7

Case 6—M K, Roentgen Ray Examination, x-ray Interpretation

Examination of the thorax shows considerable increase in the size and density of the hilus with lymphoid nodules both here as well as in the central lung field, suggesting a hilus and central tuberculosis

Diagnosis Hilus and Central T B

(7) E G, male, age 9 years *Attacks of* asthma every few days, has a positive tuberculin test, and is at present in a tuberculosis sanatorium Brother has been in a tuberculosis sanatorium and has had several attacks of pulmonary hemorrhage Another brother, age 3 years, has a positive tuberculin test We are unable to find the source of infection

Case 7—E G, Roentgen Ray Examination, x-ray Interpretation

Examination shows a considerable increase in size and density of the hilus, the mottling and nodulation sufficient to suggest a lymphatic infiltrative process in all probability tuberculous This infiltration has encroached a considerable distance on the central lung field mainly along the root branches resulting in root branch and central bronchial thickening This is fairly uniform throughout the central lung field, somewhat more marked on the right side, evidently an infantile type extension of the hilus lesion

(8) H C L, male, age 8 months, admitted to Babies Ward, March 29, 1927, case No 23064 He was sent to us with a diagnosis of asthma Chief Complaint

(1) Fever for past month

(2) Cough

A PERFORATED DUODENAL ULCER IN A CASE OF PEMPHIGUS*

BY OSCAR L LEVIN, M D, NEW YORK, N Y

IN reporting this case of pemphigus in which the autopsy revealed the presence of a perforated duodenal ulcer, I am not attempting to point out any causal relationship between the two conditions Rather, I wish to stress the fact that in the case of a baffling disease like pemphigus, of which we have scant statistical data because of its comparatively rare occurrence, much might be added to our knowledge of the condition, if an attempt were made to have more thorough clinical evidence assembled, and autopsies performed in every case More particularly, any unusual findings, whether they be considered significant or not, should be placed on record, so that we may be fully aware of any and all possible complications

It occurred to me upon learning of the presence of the perforated duodenal ulcer in the case reported here, that since ulceration of the gastro-intestinal tract following severe external burns was not an uncommon occurrence, perhaps if we had more post-mortem data and better clinical information about pemphigus and its complications, we might learn that there is more than mere coincidence in the finding of ulcerations of the lining of the gastro-intestinal tract in this condition

A thorough search of the literature revealed only one reported case of pemphigus in which a duodenal ulcer was present The case in point is that of Goldenberg and Highman[1] It is interesting to note that in their report of thirty cases of various types of pemphigus observed during five years at the Mount Sinai Hospital, only two necropsies were performed, and one of these revealed the presence of an ulcer of the duodenum

Several writers on the subject of pemphigus make mention of the fact that since the seat of origin of the disease is so often the mucous membrane of the mouth, pharynx, or larynx, it is not unlikely that the mucous lining of the digestive tract is involved further down

Morris[2] actually includes among the possible complications of pemphigus, Bright's disease, pneumonia, tuberculosis, and "ulceration of the intestinal follicles"

Pusey[3] states that the lesions may occur anywhere in the body "and presumably in the stomach"

Schamberg[4] goes so far as to say that pemphigus leads to a fatal end "often through complications of the intestinal or respiratory mucous membranes"

But only these vague references to the involvement of the intestinal tract are the most that can be found in the literature on the disease

On the other hand, in the case of severe burns, there is a fair amount of literature reporting ulceration of the intestinal tract. In 1842, Curling[5] reported twelve such cases where autopsy revealed acute ulceration In all of his patients the lesions found were in the duodenum near the pylorus Since then autopsies have revealed in numerous cases either a severe inflammation of the lining of the gastrointestinal tract or ulceration

Rouchese[6], as a result of his observations in three hundred and forty-eight cases of burned persons, believed the causal relation of burns to the ulcers was doubtful But, on the whole, the general opinion of men who have had experience in this field, is that duodenal ulceration occurs in about five per cent. of the fatal cases of severe burns The ulcers are nearly always found in the first part of the duodenum Although the mechanism of the production of these ulcers is not yet known, the explanation offered is that excretion of toxic material into the gastro-intestinal lumen takes place, and that the mucous lining is thereby injured, causing ulceration

In the following instance of a perforated duodenal ulcer found upon autopsy, in a case of typical pemphigus, the question arises as to whether as in burns, the ulcer was a complication induced by the disease, and would not

* Read at the Annual Meeting of the Medical Society of the State of New York, at Albany N Y, May 23 1928.

Rach[12] and Peshkin and Fineman[21] are of the same opinion as to the mechanism of the asthmatic attacks Our work, however, has led us to believe that the asthma is due to a sensitization on the part of the individual to the bacterial products of the tubercle bacilli probably tuberculin

In support of our belief we offer the following

Tuberculin Therapy for the asthma was given in a series of 30 cases to children presenting asthmatic symptoms, a positive tuberculin test and who did not respond to the routine asthma treatment. The results obtained were so encouraging that we are continuing this form of therapy and more complete data will be published at some future date We wish to emphasize that we do not routinely give tuberculin therapy to asthmatic children with a positive tuberculin test and that when it is given it is only from the standpoint of desensitization It is only after all the skin tests have been performed and the routine asthma treatment has failed, that tuberculin therapy is instituted, for not all asthmatic children with a positive tuberculin test have their asthma dependent upon the tuberculous focus The routine treatment mentioned includes foreign protein such as peptone The tuberculin therapy in many instances acted almost like a specific In several the relief was almost instantaneous with no more attacks In others improvement was evident after the Mantoux was done and before Tuberculin Therapy was given, while in still others the tuberculin therapy had caused the attacks of asthma to decrease both in frequency and intensity In several instances where, thru error or otherwise, too much tuberculin was given the asthmatic condition was greatly aggravated and if the patient had been asthma free for a period it reappeared If the asthma was due to obstruction it is difficult to understand how the obstruction could disappear in so short a time Comparison of the x-ray films taken before and after tuberculin therapy had either cured or improved the asthma showed no appreciable change in the size or amount of shadow or pathology in the hilum If there was an obstruction the tuberculin therapy cured or improved the asthma with the obstruction remaining, and if there was not an obstruction how then can we explain the asthma?

The mechanism of the asthma dependent upon a tuberculous focus in the Tracheo-bronchial glands and the good results obtained with tuberculin therapy could be explained on the basis of sensitivity and specificity However, we can also conceive how obstruction from the tracheo-bronchial glands may produce asthmatic symptoms This may have occurred in a few of our cases that did not respond to tuberculin therapy and who were of the advanced juvenile type, for we have found that those with the least amount of pathology responded most readily to tuberculin therapy Either the asthma in the above instances was due to obstruction or the cases were too far advanced to respond to tuberculin therapy Eiman[22] in a very recent publication states "some of the secretion proteins or their split products and bacterial proteins may become reabsorbed through the injured walls of the bronchi and thereby bring about a sensitization of the individual to his own secretion" "A similar sequence of events may develop in sinus infections" Horton Casparis[25] considers a tuberculous focus somewhere in the body as the underlying factor in phlyctenular kerato conjunctivitis and that it is a local manifestation of hypersensitiveness of the individual to tuberculin All of the children gave a positive tuberculin reaction Eighteen patients with phlyctenular-kerato-conjunctivitis were treated with tuberculin subcutaneously and in every instance positive relief began immediately

We believe that an analogous process takes place in the case of tuberculosis and asthma.

We wish to expound the theory that asthmatic symptoms in tuberculous children excepting those due to other known causes are due to a sensitization on the part of the individual to the tuberculous bacterial antigen, protein or toxic products contained in tuberculin or to a sensitization to tuberculin as a whole

It is apparent that in view of the high incidence of tuberculous infection, the many histories of tuberculous contact, the frequent finding of physical signs of the juvenile and early adult types of tuberculosis, the x-ray findings, the numerous histories of sanatorium care among the children presenting symptoms of asthma, together with the results obtained with tuberculin therapy, we must conclude that there exists a relationship which cannot be denied This relationship demands more attention, so that proper measures may be instituted for the treatment of the tuberculous infection, which is being masked by the asthmatic symptoms and thus present its getting beyond control

*The authors are indebted to D W H Meyer for the interpretation of the X Ray Plates and to Mrs. C B Adams for her generous assistance.

The blood examination on September 30, 1927, revealed 80% hemoglobin, and 5,200 white blood corpuscles The differential cell count gave the following results polymorphonuclear leukocytes, 79%, lymphocytes, 16%, mononuclear leukocytes, 1%, eosinophiles, 1%, myelocytes, 2%, and myeloblasts, 1%

The urine was clear, of acid reaction, had a specific gravity of 1 012-1 014, and was negative for albumin, sugar and acetone Occasional white blood corpuscles, epithelial cells and a few hyaline casts were present

Further Course of the Disease

The patient was hospitalized on August 23, 1927, and treatment consisted of bland ointments, luminal, bromides, and morphine for pain, and wet dressings of potassium permanganate for the fingers On August 25th, daily injections of a 2% solution of sodium arsenite were begun, starting with five minims, and increasing the dose daily by one drop *X*-ray therapy was begun on August 27th, and a note made by one of the internes states that since these treatments were instituted the results obtained were beyond expectations On September 8, 1927, only two weeks after her admission, the face, trunk and hands were markedly improved The lesions showed a tendency to dry and were less inflammatory The patient stated that she felt much better, but complained of slight itching The next week, progress was still favorable, but on September 20, 1927, a new crop of bullae appeared on the forearms and face After three days, these began to desiccate, but new lesions were still appearing *X*-ray therapy was continued On September 25th, new lesions appeared on the trunk and extremities, and the patient complained of "sticking" pains over the chest and abdomen The next day at six P M, she vomited small particles Her nausea was relieved by peppermint powder, but at six forty-five P M, she vomited twelve drams of light brown fluid During the next four days she had three or four attacks of vomiting, which seemed to bear no relation to the ingestion of food On September 30, a soap-sud enema caused much flatus and some fecal particles were washed out She complained of tenderness and excruciating pain in the right halt of the abdomen, but rigidity was difficult to determine She also suffered from dyspnoea At this time Dr Goldenberg suggested the possibility of a surgical abdomen but it was agreed that she was in no condition to be operated upon Her temperature pulse and respiration were unaffected At nine P M she was given twenty grains of sodium bicarbonate internally and a suppository of one grain of codein and five grains of aspirin were inserted At four A M, she again complained of pain in the side and at ten A M she received a low enema The next day at two-fifteen P M she was perspiring profusely, and dyspnoea was more marked She was cyanotic, but her pulse was of good quality One hour later she was unconscious Adrenalin, caffein and digitalis were administered, but at four-ten P M, breathing ceased.

AUTOPSY FINDINGS

General

The body was that of a fairly well-nourished, well-developed, middle-aged, white woman in incomplete rigor mortis Numerous skin lesions were scattered over the entire body The most typical of these were superficial bullae, containing non-purulent, slightly yellowish fluid Some of these were ulcerated and presented weeping, reddish bases which did not extend deeply into the skin These were apparently the remains of ruptured bullae They were aggregated and covered almost the entire abdominal, thoracic and posterior surfaces of the body They were extraordinarily fetid The lesions were also present on the scalp, eyelids, face, lips, nose, anterior and posterior cervical regions, vulva and buttocks The lesions on the anterior tibial region were more discrete and about the size of a pea. No evidence of induration was present The abdomen showed a midline scar and a linear one on the left loin

Abdomen

The panniculus adiposum was very well developed Numerous fibrous thickened strands were found throughout this tissue On opening the peritoneal cavity, a large amount of dark, brownish-red, clear fluid was seen Some oil drops floated in the fluid There was no evidence of either collapsed or dilated loops of gut A fluid which was present in both upper gutters and the pelvis, was pailed out and it was noticed that a similar fluid containing coffee-ground material, welled out of a punched out opening in the anterior wall of the duodenum There was no peritoneal reaction about the site of this opening, except for a few easily separated, thin, fibrinous adhesions, extending to the gall-bladder There was a similar thin, fibrinous peritoneal exudate over the cecum and a few loops of ileum The remainder of the peritoneum was smooth and glistening, except for the region immediately about the cecum where an exudate similar to the one described was noticed There was no evidence of localized peritonitis or walling off of the infection The omentum was in its normal position

have developed had there been no pemphigus, or, whether the ulcer had been present previous to the onset of pemphigus, and was made worse by the disease

Report of Case

History—R F, a female, white, Hebrew, aged thirty-six, born in the United States, was admitted to the Mount Sinai Hospital on August 23rd, 1927, with a diagnosis of pemphigus During her life she had resided in Toledo, Ohio, and New York City Her habits were regular, and there was no history of any illness during infancy or childhood The family history was irrelevant and revealed no instance of a skin complaint The patient had been married seventeen years, and two children, aged sixteen and fourteen, were living and well There were no miscarriages and no venereal history could be ascertained In 1914, she had had a nephrectomy performed by Dr A A Berg, at the Mount Sinai Hospital, for a nephritis of pregnancy Her recovery was uneventful In 1915, an operation was performed in Toledo, Ohio, for the removal of a tumor from the right lower quadrant of the abdomen, but the character of the growth was unknown In 1925, a complete hysterectomy was done at the Lebanon Hospital Recovery was uneventful The patient has not menstruated since

History of Cutaneous Condition—Before I was called into consultation, the patient had been under treatment for six weeks by her family physician, who had made a diagnosis of erythema bullosum She was admitted to the Mount Sinai Hospital with a diagnosis of pemphigus According to the patient's statement, several months prior to her admission to the hospital, a plate of false teeth fell into a sink, containing a cleaning fluid She lifted out the plate, washed it thoroughly with water and replaced it in her mouth The very next morning a few blisters appeared in her mouth, causing her some pain These lesions increased in number, spread over her cheeks and tongue, and made swallowing and breathing almost impossible In about a week the mouth lesions subsided, and a "pimple" appeared on the left naso-labial fold The lesions recurred, spread and ulcerated One week before her admission to the hospital the extremities, chest, abdomen, rectum and vagina had become involved There were ulceration, pain and fetidness

Physical Examination

The patient, a middle-aged woman, was lying in bed, and complained of pain over the areas showing skin lesions She looked quite ill, and a foul odor surrounded her Her temperature was 101° Fahrenheit, pulse rate 100, and respiration 24 per minute

It was difficult to examine the lungs because of the painful condition of the skin An occasional moist rale at the bases could be detected, but there was no dullness No change in voice or breath sounds was noted The heart was not enlarged, and a soft short systolic blow over the base was not transmitted Examination revealed a nephrectomy scar on the left side, a midline abdominal scar, the result of a hysterectomy, and a right inguinal scar, where the tumor had been removed The viscera were not palpable, and there was no tenderness, except over the ulcerated skin Because the patient complained of pain, the examination about the umbilicus and over the buttocks was very unsatisfactory

Dermatologic Examination

The main lesion on the skin was a bulla arising from apparently normal skin or on an erythematous base The lesions varied in size from a pinhead to that of a walnut The smaller lesions were tense while the larger bullae, as on the fingers, were flaccid, and the tops tended to fall over Their contents at first clear, rapidly became cloudy and pustular in character The entire skin showed a generalized eruption of such lesions, which when they broke left discrete and confluent ulcerated areas The palpebral margins of the eyes were covered with crusted remains of bullae There was a moderately severe conjunctivitis of the left eye, but there were no definite lesions on the conjunctivae The mucous membrane of the nose, as far as could be seen, was covered with crusted lesions, probably the remains of bullae Breathing through the nose was difficult because of the obstruction, and upon removal of the crusts bleeding was produced The external ears and the neck were involved with similar lesions Large superficial ulcers covered the chest The condition was worse in the folds of skin, as under the breasts

The hands, palms, fingers, and forearms showed large, flaccid and tense bullae, varying in size from that of a pinhead to about three-fourths of an inch These were filled with turbid and yellow purulent material On the lower extremities there were a few ulcerated bullae between the toes and over the upper part of the thighs Only an incomplete examination could be made of the rectum and vagina, but it could readily be seen that these parts were involved

Laboratory Examination

Pus taken from a punctured bulla on September 2, 1927, showed polynuclear cells and gram positive cocci

slightly narrowed, but the lumen of the coronary arteries showed no atherosclerotic plaques In fact it appeared to be wider than normal The aorta was elastic and showed only a few atherosclerotic plaques, more marked near the arch, about the coronary arteries There was no myocardial fibrosis

Microscopic Examination

Under the microscope the spleen showed hypoplasia of the Malpighian corpuscles The pulp was very cellular, and there were a number of cells containing brown pigment. The sinus endothelium was prominent and there was general congestion There was no iron reaction

The skin revealed congestion of the subcutis and localized areas of edema with bullous formation The lungs showed emphysema with edema and atalectasis The adrenal glands were autolyzed, but the pancreas was normal The liver was extremely fatty and the fat globules were very large, especially in the periphery of the lobule The liver cords were extremely thin The korpffer cells were swollen and prominent everywhere and contained black pigment in fine particles There was no iron reaction

The gall-bladder contained brown pigment and was normal in every other respect. The colon and the one kidney which was present, were both normal A small area in the duodenum showed the base of the ulcer with necrosis of glands and infiltration of the mucosa and submucosa with polymorphonuclear leukocytes

Summary and Conclusions

A report is here made of a typical case of pemphigus, in which the lesions first appeared in the mouth, and which was followed rapidly by a generalized bullous eruption The cutaneous reaction was unusually intense, the bullae were enormous, widely disseminated and resulted in large denuded areas This was accompanied by clinical evidences of a severe toxemia For five days the patient complained of indefinite gastro-intestinal symptoms and death occurred from a perforated duodenal ulcer Dr Goldenberg, because of his own experience with the finding of a duodenal ulcer in one of his cases of pemphigus, had suggested such a possibility

In the case here reported, it is a moot question in my mind, whether the ulcer resulted from the pemphigus, and would not have developed had there been no pemphigus, or whether the ulcer had been present and was only rendered worse by the products of the disease.

Since pemphigus is not a very common disease, and autopsies are comparatively infrequently made, thereby limiting our knowledge of the possible complications that might be encountered in this disease, it is rather difficult, in my opinion, to come to any definite conclusion about the unusual finding of a perforated duodenal ulcer It may be true that the presence of the ulcer in this case indicates no relationship to the disease, but the point which I wish to make is that perhaps when our knowledge of pemphigus and its complications is increased by more definite statistics of the possible findings, we may learn that ulceration of the lining of the gastro-intestinal tract in pemphigus is not purely coincidental

URTICARIA, THE SEARCH FOR AN UNDERLYING AGENT*

BY R. H RULISON, M D., AND JULIA V LICHTENSTEIN, M. D, NEW YORK, N Y
From the Department of Dermatology and Syphilis, Cornell Clinic

IMMUNOLOGISTS feel that all the phenomena of the urticarial group of diseases will ultimately be explained and controlled by their methods Gastro-enterologists and bacteriologists are heartened by recent reports of success in treating urticaria by correcting abnormal conditions in the bile passages, while surgeons stand ready to remove foci of infection wherever they may be found

Without minimizing the very real help which often follows any of these methods of handling chronic urticaria, dermatologists are often faced with the problem of relieving those patients who exhibit no discoverable exogenous cause for their symptoms It seems to us that the successful treatment of chronic urticaria will involve a better understanding of its mechanism within the body and therapy directed toward the control of this mechanism Recently acquired knowledge in regard to physiology of the blood vessels and in

*Read at the Annual Meeting of the Medical Society of the State of New York, at Albany, N Y, May 22, 1928.

Gastro-intestinal Tract

The oesophagus was normal The stomach wall was somewhat thickened, and its mucosa was normal, but of a rather pale color There was no flattening of the rugae, neither were there any ulcerations nor changes in the peritoneal coat. In the region of the first portion of the duodenum, at its anterior surface, about one and a half centimeters from the pyloric sphincter, there was a punched out ulcer with overhanging margins The base of this ulcer was formed in its upper portion by the muscular layer of the duodenum, but in its inferior portion there was an opening which entered directly into the peritoneal cavity The margins of this ulcer were indurated for about one and a half centimeters about its periphery There were no enlarged glands in the lesser omentum or portio hepatis No evidence of a walling-off process about the perforation from the peritoneal side could be seen, except for the few gall-bladder adhesions already mentioned The duodenum contained a large amount of coffee-ground material The rest of the gastro-intestinal tract showed the remains of old blood, but otherwise nothing abnormal The mesenteric lymph nodes were normal

Liver and Gall-bladder

The liver weighed 1,520 grams, was normal in size and shape and had a light yellowish-brown appearance Glison's capsule was everywhere smooth and glistening The margins of the lobes were neither sharp nor especially round A cut section revealed a distinct lobular structure in which the central veins were quite prominent, and the liver tissue about it appeared yellowish On squeezing the gall-bladder, bile was expressed into the duodenum The wall and mucosa of the gall-bladder were apparently normal, but the gall-bladder contained a dark viscid bile and several black, pigmented stones about the size of cherry pits The portal vein contained fluid blood

Spleen

The spleen weighed seventy-five grams and was small in size Its capsule was wrinkled and the organ was soft and could be folded upon itself A cut section revealed an intensely red surface in which the trabeculae were increased The Malpighian bodies were not easily seen and the pulp did not scrape

Kidneys

Only the right kidney was present This weighed one hundred and sixty grams There was a large perinephritic fat body The capsule stripped easily and revealed slightly wider than normal cortex and medulla The cortical markings were distinct as were also those of the medulla The kidney was slightly softer in consistency than normal The right pelvis and ureter were normal The left kidney was absent and replaced by fibrous and fat tissue. The left ureter was also absent. The bladder was rather small and contracted, but its mucosa was normal, except for some slight trabeculation The right ureter could be probed very easily through the orifice of the bladder, but though the left urethral eminence was seen in the bladder, its lumen was obliterated

Uterus and Adnexae

The vagina showed nothing abnormal The cervix was hard and showed some old lacerations The supracervical portion of the uterus, the tubes and ovaries were all absent. There was a healed scar in the peritoneum running down from the lateral walls and attached to the cervix

Chest

There was no free fluid in either of the pleural cavities There were strong adhesions at both apices and in the region of the left lower lobe, but the remainder of the cavity was smooth and glistening Deep scars could be seen in both apices There was a fibrocaseous nodule at the left apex and at the upper portion of the left lower lobe On incision, a thick caseous material escaped from these walled-off areas and there were some scars beneath them All the lobes of the lungs were unusually well aerated Numerous bleb-like areas collapsed on incision The cut surface was very dry In the region of both lower lobes there were some areas which were not well-aerated and somewhat fleshy in consistency They were very slightly raised above the remaining tissue on the cut surface No granular nor cloudy fluid could be expressed The pulmonary artery showed no gross atherosclerosis either in its larger or finer branches The bronchi were pale The larger branches contained the coffee-ground material already described in the oesophagus, but this did not extend into the small bronchi The right lung weighed three hundred grams, and the left two hundred and ten grams The tracheobronchial lymph nodes were not enlarged

Thyroid

This gland was normal in every respect.

Heart

The organ weighed two hundred and fifty grams, and was of normal size The left ventricle was markedly contracted and very firm The right ventricle was slightly dilated and its myocardium was flabby The valves were entirely normal The orifices of the coronary artery were

without causing symptoms When, however, the substance is given off in concentrated form it acts as a capillary poison from outside the capillary, producing in its immediate vicinity a local condition of edema Lewis' experiments are exhaustive and it seems difficult to account for the observed facts on any other basis If his work is generally accepted urticaria will be explained as a local response to the excessive release of a normal metabolite, either histamine or some histamine-like substance

One of the puzzling things connected with the study of urticaria is the great variety of exciting agents known to produce the same response in different individuals If we can think of these substances as exciting agents *only*, causing their effects through the release of an increased amount of some normal product of cell life, a step toward the better understanding of urticaria may have been made.

Before it can be proved that histamine or some histamine-like substance is the underlying agent in urticaria it will probably be necessary to have available a simple and delicate quantitative test for the substance Also, it must be admitted that histamine injected intravenously does not produce urticaria, possibly because the resulting transudation is so widespread and uniform

Assuming that histamine is the underlying agent in urticaria two methods of treatment seem logical (1) a diminution of the patient's response to this poison, and (2) the prevention of its release in excessive concentration

To reproduce a given degree of experimental shock it has been found that the second dose of histamine must be much larger than the first We, therefore, attempted to diminish the response of a group of cases of chronic urticaria by successive subcutaneous injections of slowly increasing doses of this substance

Seven patients were treated for periods varying from three weeks to four months One-tenth cc of a 1-1000 dilution of histamine was injected subcutaneously and the dose was increased gradually by 0 05 cc until 0 3 cc was reached The amount was not further increased as the response of the patients became too acute In the beginning the injections were given once a week or, in a few cases, twice a week During this period, covering ten weeks, both patients and physicians felt that progress was being made Reactions from injections diminished in intensity, the fall in blood pressure became less or ceased, and the patients reported clinical improvement At this stage the number of injections per week was increased to three Thereafter the patients failed to improve and in some instances seemed definitely worse The failure in this series of cases may have been due to impatience on the part of the experimenters or to a mistaken line of experimentation

Following the second line of approach, it was felt that the release of the toxic substance in excessive concentration might be prevented by making the cells less permeable In a general way the inherent protoplasmic reaction of living cells is known When stimulated they show lessened turgor, lowered surface tension, greater permeability, lowered surface charge, lessened calcium and increased potassium content Peterson and Wallis in a study of variations in the time of blister formation concluded that "there is a direct chemical basis for the difference in permeability and inflammatory response, namely the ratio of calcium to potassium" "The impermeable cell has," they think, "a greater amount of calcium in proportion to its potassium, while the permeable cell has a small amount of calcium in proportion to its potassium"

The effectiveness of calcium in the treatment of urticaria has been seriously questioned, for it has been repeatedly observed that the calcium content of the blood serum in this disease is within normal limits Nevertheless, it was felt that the use of calcium might be justified theoretically as well as empirically since it is thought to decrease cell permeability, reduce hypersensitiveness of the nerves and tends to maintain calcium potassium equilibrium The only dermatologist we know who feels satisfied with his treatment of urticaria gets his results by the intravenous use of calcium chloride urea (Afenil) We are now treating a group of chronic urticarias with calcium by mouth and by intravenous injections So far all but one case show marked improvement.

In recent literature the phrase "physio-chemical equilibrium" is often used It is applied to the condition of a hypersensitive patient who temporarily is free from symptoms The writers feel that, although their work up to this point has been inconclusive, the newer conception of the mechanism of urticaria may lead to the discovery of some way of restoring and maintaining this physio-chemical balance

Krogh A The Anatomy and Physiology of Capillaries Yale Univ Press, New Haven (1924)

biochemistry is of considerable assistance in this matter

The phenomena of urticaria depend on the development of extracellular edema Edema depends on increased capillary permeability If the circulatory system is though of as consisting of a propulsive organ, the heart, a conducting system, the arteries and veins, and a permeable system, the capillaries, in which the blood performs its work of cleansing and nourishing the body tissues, the tremendous importance of the capillaries becomes evident

Until twenty years ago the capillaries were thought of as simple endothelial tubes whose action was controlled by the condition of the arteries on the one side and the veins on the other Efforts to explain certain striking conditions, such as traumatic shock, on the basis of alterations in the vaso-motor mechanism, as it had been understood, were found to be inadequate and an intensive study of the capillaries followed

The first important observation was that the capillaries are not simple endothelial tubes but are partially covered by contractile cells (Rouget cells) These cells are probably concerned in the regulation of the size of the capillaries The second observation was contributed by Krogh who found 85 open capillaries per square millimeter in guinea-pig muscle when the animal was at rest as compared with 2500 open capillaries per square millimeter in active animals The third observation, made by a number of independent workers, was that the capillary tone can be varied without the intervention of the nervous system and seems to be determined by local conditions within and without the capillary endothelium A fourth discovery was that a group of substances acted as capillary poisons, causing increased permeability and dilatation These new observations enable us to visualize the mechanism of the production of edema Also we are able to explain the fall of blood pressure which accompanies both traumatic shock and urticaria not on the basis of a loss of tone of the vasomotor system, but through the tremendous increase in the number of open capillaries and their degree of dilatation and permeability

Ebbeke says "Urticaria and shock can be explained on the same basis, by considering the effect of the substances that produce them on the capillaries and the capillary circulation. There can be different degrees of the urticarial reaction and different degrees of shock depending upon the degree of capillary dilatation The substances producing both are products of cell metabolism (protein products resulting from irritation or destruction of the cells and present in the local or general circulation in abnormally increased quantities The relief of such conditions depends on shutting off the source of the toxins, increasing the capillary tonus and relieving the capillary hyperemia"

The Committee on Wound Shock and Allied Conditions during the war weighed and discarded many of the older conceptions of shock and Cannon, in 1923, published his book on Traumatic Shock embodying the results of this work His conclusions are that shock results from the absorption into the circulation of the products of cell destruction, that these products are toxic, causing paralysis of the capillaries, increased permeability, loss of plasma into the surrounding tissues, loss of blood volume, concentration of the blood, deficient return of venous blood to the heart, and a consequent fall of blood pressure in spite of the efforts of the vasomotor center to compensate for the loss of volume by constriction of the larger vessels

The exact substance in traumatized tissue which thus acts as a capillary poison is still undetermined It may be that there are more than one However, the work of Dale, Laidlaw, Richards and others on histamine shock indicates that this substance or some similar product of cell metabolism is the active agent

Histamine is the most powerful of the amines and a typical capillary poison It is produced by decarboxylation of histidine, one of the amino acids It has been recovered from the intestine, the liver, the lungs and is probably present in all tissues In extreme dilution it is non-toxic Introduced into the circulation it causes shock The degree of shock produced depends on the amount of the substance and the rapidity with which it is injected In animals it reproduces with surprising accuracy the symptoms of anaphylactic shock, in man those of traumatic shock When injected subcutaneously in 1-1000 dilution, even in minute dosage, it produces a typical urticarial wheal locally and causes a fall in blood pressure, flushing of the face and neck and a feeling of giddiness

Histamine causes contraction of unstriped muscle and dilatation of the capillaries Since Landis has recently shown that dilatation alone is insufficient to cause transudation of plasma and since edema follows the use of histamine it is evident that a poisoning of the endothelial cells accompanies the paralysis of the Rouget cells of the capillaries This poisoning of the capillaries may be temporary, as occurs in urticaria and in mild shock or it may be permanent, resulting in gangrene as found in chronic ergotism It is well known that histamine is the active constituent of ergot.

In wound shock the poisonous substance is probably released by the injured cells and taken up by the blood stream, poisoning the capillaries from within Lewis, after a long series of experiments, has concluded that a substance closely related to histamine is a normal product of cell metabolism, that when this is released in normal amount it is rapidly diluted by the tissue fluids, finds it way into the circulation and is destroyed

by three glasses of milk together with six glasses of soft drinking water each day

As the patient improves in general strength, exposure of the entire body to the actinic rays of the sun or of the Quartz lamp, together with massage, constitute helpful measures The light exposures should be very brief at first, such as three or four minutes at each session, lest the patient's surfaces be irritated, and interference with sleep result

Change of scene, climate and surroundings is very helpful, as early as it can possibly be instituted, by removing a patient living at the sea level to an inland point, and removal to the seashore of the patient who lives on higher ground inland

Probably the best results are obtained at a well equipped health resort, where an atmosphere of cheer, available proper food, a routine life and careful nursing are features, and peace and quiet prevail In no morbid condition is the scriptural injunction more applicable than during the depressed condition to which close attention is necessary, to wit, "Despise not thou the day of small things," for each little added annoyance increased impatience and distress, which, in turn, sap the reduced nerve force and often defeat the attempt to secure extra sleep The nurse, therefore, must be warned by the doctor to look out for crumbs, wrinkles in bed clothing, unpleasant odors, unnecessary noises, all visitation except the most judicious, want of ventilation, and any interference with practically constant companionship of the quietest nature for the patient.

STUDIES IN URTICARIA*

BY ABRAHAM WALZER, M D., BROOKLYN, N Y

From the Department of Dermatology and Syphilology Good Samaritan Dispensary, New York City, and the Jewish Hospital of Brooklyn, N Y

THE employment of immunological principles to explain pathological skin conditions is not by any means new Many dermatological diseases have either been suspected or have been known to be manifestations of hypersensitive phenomena for a long time. Among these are many of the erythemas, the urticarias, the eczemas, and a number of other dermatosis, as dermatitis venenata, dermatitis medicamentosa, etc

It was the urticarias that we decided to study first for the reason that we have found a way of experimentally reproducing the wheals of a constitutional urticaria in a natural manner This method of wheal production, as we have previously explained, was first suggested to us by the work of Prausnitz and Küstner, who demonstrated that an intradermal injection of certain hypersensitive patients' serums into the skin of a normal individual, temporarily sensitizes that injected site to the same substance to which the patient is sensitive A wheal can be elicited at that site by the direct local intradermal injection of the offending protein

We went a step further and showed that with the employment of serums of certain food hypersensitive patients the wheal could also be elicited at the passively sensitized site by the oral or rectal administration of the offending food to the passively sensitized subject, and in this way simulating the mechanism of a constitutional urticaria

1 *Types of Urticaria*

In the course of our experimental studies, we examined many cases of urticaria for clues to the offending factor We found that the patients in whom the specific excitant was identified, could be divided into two groups

Group I Urticarias whose etiology was definitely demonstrated by skin tests for hypersensitiveness

Group II Urticarias whose etiology was determined chiefly by history, and only occasionally confirmed by skin tests

There was still another group of cases in whom the etiology could not be determined in spite of the most careful history and complete sensitization tests This phase of the question will be taken up at some future date.

2 *The Differences Between Both Groups of Urticarias*

The patients of group I differed from those of group II in the following chief characteristics (1) they all gave positive skin tests for the specific offending factor, (2) removal of the excitant cleared up the symptoms, (3) besides the skin manifestations, many of these patients showed mucous membrane involvement of either of the respiratory tract in the form of "frequent colds," as rhinitis, hayfever, asthma etc., or they had associated gastro-intestinal disturbances as "acute indigestion," "frequent vomiting" etc., (4) the "antibody" (reagin) could be demonstrated in the blood stream, and for this reason their sensitivity could be transferred by means of their serum to skin sites on normal individuals, in whom wheals could be induced by the direct local testing of the sensitized area, and in some subjects, also by the ingestion or rectal administration of the offending food

AFTERCARE OF INFLUENZA CASES*

BY ALBERT WARREN FERRIS, M.D, F.A.C.P., WATKINS GLEN, N Y

SINCE 1889, influenza has been endemic in this country, few sporadic cases in various parts of our territory being followed by widespread outbreaks and very numerous instances, varying in attack and course, and often difficult of diagnosis

The recent and continuing recrudescence which appeared in many parts of the country and, indeed, in many parts of the world, has not been noted for great mortality except in Great Britain, but it is generally reported that a large majority of the cases have been characterized by deep depression, during or immediately after the febrile or bronchial phase of the disease, for we must consider the depression, whenever occurring, as part of the attack, and as due to the action of the toxines of the disease upon the cerebrum

It is reported from many quarters that this depression consists not only of disappointment and chagrin, with impatience and irritability, but also of general dread, special fears without reasonable foundation, and even morbid thoughts including fear of impending catastrophe and suicidal impulse In fact, several instances of suicide have been reported in recovering or apparently recovered cases

The most understanding and devoted care by physician and nurse is essential in all these depressions, if the duration of the condition is to be shortened and the nerve reserve of the patient is to be increased and conserved For the nurse to wait until the patient asks for definite ministration is not sufficient, nor is it adequate for the physician to order close care and attention. Definite and practical directions are necessary, and these the physician must supply

Before the medical adviser lies a wide field for psychotherapy Daily encouragement and good cheer are necessary, together with assurance of improvement to come, and with the statement that depression in these cases is of very usual occurrence and that it is by no means an unfavorable symptom It should be explained to the patient that it is a result of the influenza poison which will be eliminated as time goes on

It is very desirable that the content of the patient's mind should be changed by substituting safe and sane ideas, for the morbid ones that he is encouraged to communicate to his physician.

In cases of this fell disease where there is little physical exhaustion, muscular activity such as walking, pitching a ball, housework, shoveling snow or earth, etc, will change the current of thought. In many other cases reading furnishes a sure mental diversion, and in most cases playing games such as with cards will give decided relief In a few cases definite intellectual exertion such as writing or dictating correspondence, or descriptive composition, give relief from mental distress, and will be followed by a natural trend of thought and mental poise and calmness, at least for a time, this diversion being repeated upon return of depression

Disturbing dread or actual depression may be relieved by administration of small amounts of black coffee repeated as frequently as necessary during the day Certain clinicians recommend Dr Harrower's preparation of Lydig cell substance, and as we know that all infectious disorders damage the thyroid gland and reduce its activity, it is wise to add to the medication, three times a day, one-fourth grain of thyroid gland substance Favorable action of the thyroid gland is also secured by the use of two or three drops of a saturated solution of potassium iodide after each meal A subnormal blood pressure calls for the administration of suprarenal substance in two grain to five grain doses

It is important that a rather large amount of food be taken by the patient, reliance being placed upon oranges, green vegetables, milk, cream, butter, cottage cheese (or cream cheese), and eggs, to the exclusion of meat, with a tablespoonful of cod liver oil at the close of the meal

Sleep is of prime importance, and it may be difficult to obtain it while lying flat, if the breathing is labored It may be secured by a patient so affected if bolstered up nearly in a sitting position A hypnotic may be necessary, one or other of the barbituric acid derivatives such as allonal, one-half to one tablet acting as a comforting sedative to prevent waste of nerve force and to induce refreshing slumber Often hot milk or malted milk at bedtime induces sleep

Elimination by skin, kidneys and bowels is essential, the skin needing least attention, and a successful digestive condition being secured by small doses of Epsom Salts or Rochelle Salts before breakfast daily Diuresis will be caused

*Read at a meeting of the Schuyler County Medical Society, Watkins Glen, May 21st, 1929

Delayed reactions are occasionally noted, but their significance is not very clear at present.

8 *The Association of Mucous Membrane Lesions with Urticaria*

In testing various types of urticaria, we noted a rather interesting relationship between positive skin tests and the urticarias with mucous membrane phenomena The association of such diseases as asthma, hayfever, gastroenteritis, etc., with urticaria very often placed that patient in group I since the offending factor was very frequently located by the skin tests As we will show shortly, it was the reagins* of such cases only, that we were able to demonstrate at the passively sensitized sites by the ingestion of the offending food

Purely local mucous membrane lesions in the mouth as erythematous macules, slight edematous erythematous patches, or abrasions, or an accompanying angioneurotic edema of the lips, tongue, etc., were occasionally noted in association with the generalized urticaria. Such patients rarely responded to testing, since they often indicated a sensitivity of the drug idiosyncrasy type, which is not responsive to skin testing In some such patients, we were, however, able through a careful history to locate the offending agent to be in the mouth washes employed by these patients, as the menthol in Listerine, and the oil of cassia in Lavoris

9 *The Demonstration of "Antibodies" or Reagins*

The only cases in which reagins were definitely demonstrated were as stated previously, the urticarias that gave positive skin tests, those of group I These patients are, therefore, the only ones whose skin manifestations were immunological in the strict sense of the term as defined by Coca —"the result of the interaction of antigen and its antibody"

We have shown that the two methods of demonstrating the reagins at the passively sensitized sites were as follows first, the method of Prausnitz and Küstner, which includes the direct injection of the antigen in the sensitized site, and, second, the modification of this method as practiced by us, namely, the oral or rectal administration of the offending food to the passively sensitized subject As stated previously, the association of mucous membrane lesions, as asthma, nayfever, etc , with the urticarias (or other hypersensitive skin manifestations as eczema, pruritus, etc.) had an important bearing on the type of reagins present in that particular case. These specific antibodies were the only ones which would allow demonstration at the passively sensitized site either by the oral or rectal administration of the offending food So far, all our experimental serums were obtained only from such patients What the connection between the mucous membrane lesions and these specific reagins is, we are not as yet ready to state

The presence or absence of demonstrable reagins is the main distinguishing characteristic feature of these two groups of urticaria Whether the mechanism of all types of urticarias is therefore alike, is problematical Group I consists of food sensitive patients, who have demonstrable reagins in the circulation, which in conjunction with their respective antigens are responsible for the urticaria They are therefore definitely immunological in mechanism

Group II is chiefly due to drugs, intoxicants, serums, etc. The active principle in drug sensitivity is not antigenic, and hence no reagins have as yet been demonstrated, or satisfactory evidence been advanced as to their existence. The mechanism of action of this group of cases is at present not understood

With this definite distinction between the two groups of urticarias, we are justified in assuming, at least for the present, that all urticarias are not due to one common mechanism of formation.

10 *Experimental Urticaria*

In our previous reports on experimental urticaria we discussed the production of wheals through internal channels We disclosed the underlying principle which is the basis for all our studies in urticaria, and also described all fundamentals regarding technic in preparation of the serum, methods of injection, etc. We showed that up to the present, we have found only two types of serums, one fish sensitive, and the other sensitive to egg, which will allow the induction of wheals at the passively sensitized site by the ingestion or rectal administration of the offending food We described the complete reaction, induced in this manner, together with its various types of pruritus, erythema and wheal on the normal skin, and showed that they corresponded clinically and morphologically to the skin reactions of a constitutional urticaria

We have also been able to reproduce these wheals on abnormal skins, and on locations where urticarial lesions are not usually seen clinically Reactions were produced on atrophia cutis, scleroderma, ichthyosis, keloid, scar, psoriasis, multiform erythema, etc., and on these locations the wheals were as a rule very prominent and distinct. We will discuss this phase of the question more fully in the near future.

In connection with wheal formation and production, the question of the mechanism of the wheal of urticaria factitia suggested itself to us We are convinced that the dermographism is not an exaggerated normal phenomenon as is claimed by a number of observers, among whom are

*Reagins Coca and Grove have suggested this term to designate the specifically reacting substances in the serum of hypersensitive individuals. They are different from the ordinary antibodies, and can best be demonstrated by the method of passive local sensitization of Prausnitz and Küstner

3 *The Relation of Heredity to Hypersensitiveness*

Heredity influence is at present recognized as a very important etiological factor for the development of hypersensitiveness in humans Positive histories can be elicited in over 50% of patients The type of symptoms, whether urticaria, asthma, hayfever, etc, as well as the age of onset of the hypersensitive manifestations is also dependent on familial influences The stronger the inheritance, the earlier will the symptoms appear

4 *Skin Tests for Urticaria*

The skin manifestations of all urticarias, whether of group I or group II are practically alike—they all show simple and polymorphous wheals of various shapes and sizes To classify them therefore, on skin lesions alone was impossible In some few instances, however, this could be done For example, it was noted that the presence of small annular or semiannular wheals, with or without surrounding erythema, indicated an urticaria usually not diagnosed by skin testing Again, angioneurotic edema is often associated with either group, but where it occurred alone, without any associated respiratory or gastro-intestinal symptoms, no positive skin tests were usually elicited Both of these types of urticarias were therefore placed under group II

Skin testing in the urticarias, therefore, was only of value as a diagnostic procedure in those patients classed under group I, because as was stated previously, these were the only cases that demonstrated positive skin reactions Even in these cases, the final decision as to the offending factor did not always rest with the skin test—it is after all the clinical test which is the deciding factor The urticaria must be relieved by the removal of that suspected excitant before it can be definitely credited as the cause of the disease

5 *Positive Skin Tests*

Only intradermal injections with freshly prepared extracts of raw unchanged proteins were performed in testing all urticarias

As has just been stated, a positive skin test does not always give the clue to the etiology for that urticaria A positive skin test may be interpreted on any of the following principles (1) it indicates the specific cause of the disease (usually a food) in that individual, (2) it might indicate a definite sensitivity, as for instance the presence of an associated asthma or gastro-enteritis, etc, but not necessarily the etiology of the urticaria, (3) it might indicate a latent sensitivity—a condition which has not yet matured, but will some day show itself by the development of hypersensitive manifestations, (4) it might indicate a pseudo-sensitivity, as a result of recent injections of horse serum (diphtheria antitoxin) Such skin test reactions are usually transient and not very marked, (5) a positive skin test might be obtained for a specific agent, and yet no symptoms develop on exposure to that excitant This is frequently observed in cases that have been treated with the gradual increasing intramuscular doses of the offending protein, and in spite of the disappearance of the hypersensitive systems, will persistently demonstrate positive skin tests, long after the patient had lost his sensitivity clinically It has been definitely demonstrated that positive skin reactions may precede or outlast clinical food sensitivity for a year or more

6 *Negative Skin Tests*

Negative skin tests on the other hand do not necessarily exclude that tested protein as the offending factor, since it is occasionally noted that the ingestion of a specific food will induce an urticaria in spite of the negative results on testing.

Negative tests may be explained on the following principles (1) A negative test may indicate a true absence of sensitivity, (2) a negative reaction might occur very early in the development of a specific protein sensitivity in a patient, but subsequent testing, however, will indicate the same antigen as the offending factor, (3) negative tests might be due to the unreliability of the extracts employed. Such reactions are frequently observed in vegetable and fruit (Strawberries) sensitive cases These extracts deteriorate rather rapidly, and unless strictly fresh extracts are used, false reactions are often obtained, (4) a negative reaction to certain proteins might occur in an urticarial patient, who, however, clinically demonstrates the etiology to be that specific food. Such a result usually indicates that the excitant is not the raw protein which is used in testing, but an altered form or split product, as a result of cooking, or to digestive or putrificative changes of that food in the gastro-intestinal tract, (5) most drugs or chemicals as bromides, aspirin, pyramidon, etc, give negative reactions, in so far as indicating a specific drug sensitivity is concerned Wheals, however, can be produced by the introdermal injection of many drugs as morphin, codeine, peptone, histamin, etc., but reaction so produced are simple factitious wheals, and will occur practically in every individual, and have no definite immunological significance.

7 *Multiple Skin Reactions*

Multiple positive skin reactions from two to five or more are frequently observed in hypersensitive individuals Usually, however, not all of these indicate the offending factor for the urticaria. Some might indicate the remains of a previous sensitivity which is dying out, others might foretell the onset of a hypersensitive group of symptoms at some future time, while still others might indicate mucous membrane sensitivities, as asthma, hayfever, etc.

Delayed reactions are occasionally noted, but their significance is not very clear at present

8 *The Association of Mucous Membrane Lesions with Urticaria*

In testing various types of urticaria, we noted a rather interesting relationship between positive skin tests and the urticarias with mucous membrane phenomena The association of such diseases as asthma, hayfever, gastroenteritis, etc., with urticaria very often placed that patient in group I since the offending factor was very frequently located by the skin tests As we will show shortly, it was the reagins* of such cases only, that we were able to demonstrate at the passively sensitized sites by the ingestion of the offending food

Purely local mucous membrane lesions in the mouth as erythematous macules, slight edematous erythematous patches, or abrasions, or an accompanying angioneurotic edema of the lips, tongue, etc., were occasionally noted in association with the generalized urticaria. Such patients rarely responded to testing, since they often indicated a sensitivity of the drug idiosyncrasy type, which is not responsive to skin testing In some such patients, we were, however, able through a careful history to locate the offending agent to be in the mouth washes employed by these patients, as the menthol in Listerine, and the oil of cassia in Lavoris

9 *The Demonstration of "Antibodies" or Reagins*

The only cases in which reagins were definitely demonstrated were as stated previously, the urticarias that gave positive skin tests, those of group I These patients are, therefore, the only ones whose skin manifestations were immunological in the strict sense of the term as defined by Coca —"the result of the interaction of antigen and its antibody"

We have shown that the two methods of demonstrating the reagins at the passively sensitized sites were as follows first, the method of Prausnitz and Küstner, which includes the direct injection of the antigen in the sensitized site, and, second, the modification of this method as practiced by us, namely, the oral or rectal administration of the offending food to the passively sensitized subject As stated previously, the association of mucous membrane lesions, as asthma, hayfever, etc, with the urticarias (or other hypersensitive skin manifestations as eczema, pruritus, etc.) had an important bearing on the type of reagins present in that particular case. These specific antibodies were the only ones which would allow demonstration at the passively sensitized site either by the oral or rectal administration of the offending food. So far, all our experimental serums were obtained only from such patients What the connection between the mucous membrane lesions and these specific reagins is, we are not as yet ready to state

The presence or absence of demonstrable reagins is the main distinguishing characteristic feature of these two groups of urticaria Whether the mechanism of all types of urticarias is therefore alike, is problematical. Group I consists of food sensitive patients, who have demonstrable reagins in the circulation, which in conjunction with their respective antigens are responsible for the urticaria They are therefore definitely immunological in mechanism

Group II is chiefly due to drugs, intoxicants, serums, etc The active principle in drug sensitivity is not antigenic, and hence no reagins have as yet been demonstrated, or satisfactory evidence been advanced as to their existence. The mechanism of action of this group of cases is at present not understood

With this definite distinction between the two groups of urticarias, we are justified in assuming, at least for the present, that all urticarias are not due to one common mechanism of formation.

10 *Experimental Urticaria*

In our previous reports on experimental urticaria we discussed the production of wheals through internal channels We disclosed the underlying principle which is the basis for all our studies in urticaria, and also described all fundamentals regarding technic in preparation of the serum, methods of injection, etc. We showed that up to the present, we have found only two types of serums, one fish sensitive, and the other sensitive to egg, which will allow the induction of wheals at the passively sensitized site by the ingestion or rectal administration of the offending food We described the complete reaction, induced in this manner, together with its various types of pruritus, erythema and wheal on the normal skin, and showed that they corresponded clinically and morphologically to the skin reactions of a constitutional urticaria

We have also been able to reproduce these wheals on abnormal skins, and on locations where urticarial lesions are not usually seen clinically Reactions were produced on atrophia cutis, scleroderma, ichthyosis, keloid, scar, psoriasis, multiform erythema, etc., and on these locations the wheals were as a rule very prominent and distinct. We will discuss this phase of the question more fully in the near future.

In connection with wheal formation and production, the question of the mechanism of the wheal of urticaria factitia suggested itself to us We are convinced that the dermographism is not an exaggerated normal phenomenon as is claimed by a number of observers, among whom are

*Reagins Coca and Grove have suggested this term to designate the specifically reacting substances in the serum of hypersensitive individuals. They are different from the ordinary antibodies, and can best be demonstrated by the method of passive local sensitization of Prausnitz and Küstner

Lewis, Krogh, and others, but is an indication of some pathological process in that patient

The question that we set out to answer was this is there a dermographism inducing principle in the blood of patients with generalized urticaria factitia, which might be demonstrated by injecting the serum of such patients into the skin of a normal individual, and then stroking the injected sites?

We accordingly selected ten of the most severe types of patients presenting urticaria factitia, and employed their serums in these tests With only one serum were we able to transfer a dermographism inducing principle to skin sites on normal individuals This would therefore suggest that the mechanism of all factitious urticarias is in all probability not similar—that, like the usual urticarias, there are also two types of dermographism, one in which the dermographism inducing principle is demonstrable by our technic, and one in which it is not

The complete experimental results with this particular dermographism inducing serum is the subject of a communication, published recently*

THE TREATMENT OF PLACENTA PRAEVIA*

BY HERVEY C WILLIAMSON, M D, NEW YORK, N Y

As there is no known preventive for placenta praevia the treatment resolves itself into curative measures

On the Cornell Division at Bellevue Hospital we have adopted a routine plan of treatment for placenta praevia When a patient is admitted with a history of vaginal hemorrhage a careful abdominal examination is made Unless there is severe bleeding, vaginal examination is withheld until preparation for operative delivery is made The reason for this is that we do not wish to remove clots and risk a fresh hemorrhage nor do we care to make an unnecessary examination because of the possibility of introducing bacteria

A diagnosis can often be made by abdominal examination The presenting part is high and the lower uterine segment feels boggy The blood pressure must be taken for evidence of shock and as a differential point in the diagnosis of accidental hemorrhage A relatively high blood pressure with albuminuria is suggestive of the latter condition The patient's blood is typed and the proper donor secured If the patient is not in shock she is prepared for operative delivery Thirty c c of 2 per cent mercurochrome solution is instilled into the vagina and an examination made to establish the diagnosis The cervix is usually sufficiently dilated to feel the placenta If a central or partial placenta praevia is found, an extra-ovular No 4 Voorhees bag is introduced Unless the baby presents by the breech an external version is performed so that the feet are easily accessible A slight gas anesthesia may be necessary for this manoeuvre The patient remains in the operating room as the bag is usually expelled into the vagina in a relatively short time We consider it very important that the surgeon in charge remain in attendance as a severe hemorrhage may occur when the bag passes into the vagina As soon as the bag has passed into the vagina the patient is anesthetized, the bag removed and another instillation of mercurochrome made The operator then introduces his hand, through the placenta in the central and at the free margin in the partial type, and brings down a foot A very slow extraction is then performed in order to prevent rupture of the lower uterine segment We do not wait for a spontaneous delivery The placenta is then expressed or removed manually and the uterus and vagina packed with iodoform gauze through a tubular packer After the uterus is packed, the cervix should be inspected and any tears that are bleeding should be sutured before the vagina is packed The fundus should be carefully watched post-partum to prevent hemorrhage behind the packing One cubic centimeter of pituitary extract should be given

Occasionally, when vaginal examination is made, sufficient cervical dilatation is present for delivery and in this case a version is done at once

If, on admission, a patient is bleeding and shows evidence of shock by the usual symptoms, she is treated in the following manner The vagina is tightly packed with iodoform gauze The patient is placed in the Trendelenburg position, morphine is given by hypodermic, tap water is instilled by rectum, saline is injected by hypodermoclysis and 500 c c of gum glucose is given intravenously A transfusion is done as soon as it can be arranged The blood pressure is taken at frequent intervals and operative delivery deferred until the systolic pressure has risen to 100 or more After recovery from shock, the patient is delivered by version and extraction as outlined above

The insertion of a bag may not be always necessary in the marginal type of placenta praevia as rupture of the membranes allows labor to be-

*Read at the Annual Meeting of the Medical Society of the State of New York, at Albany N Y, May 23 1928

gin and the presenting part controls the bleeding In four of our cases rupture of the membranes was sufficient to induce labor and in three rupture of the membranes followed by the introduction of a bag Under these circumstances the bag is inserted in the intra-ovular position In only four of our cases of marginal placenta praevia was operative delivery necessary following the expulsion of the bag

Cesarean section is employed only in carefully selected cases of central and partial placenta praevia The patient suitable for the operation is one who is not in shock, who has suffered no severe blood loss and upon whom no vaginal examination or manipulation has been made prior to admission The proximity of the placenta to the cervix makes infection an easy matter

The use of vaginal hysterotomy in the treatment of placenta praevia should be limited to cases in the fifth to sixth month of pregnancy in which the cervix is long and tightly closed There were two cases in this series, both about sixth months pregnant, that were satisfactorily delivered by this operation.

During the treatment of patients with this grave complication frequent blood pressure readings should be taken We believe that this is the most valuable criterion for the determination of shock. If the systolic pressure is 90 or below immediate measures, as outlined above, are instituted Arrangement for transfusion should always be made and if there has been a copious hemorrhage antepartum, it is imperative to give it before delivery with possibly another afterward We require the attending surgeon to remain with the patient until delivery is complete, and the patient transfused and out of shock

Statistics

Sixty-five cases of placenta praevia were treated during the five year period 1922 through 1927 There were five maternal deaths, fourteen infant deaths and seventeen stillbirths

Thirty-one patients were treated by the use of the bag, version, extraction and packing, as described above Eleven were found to be sufficiently dilated for immediate vaginal delivery, either by version and extraction, breech extraction or forceps

There were five cesarean sections, four of the low classical operations and one of the low cervical type Two vaginal hysterotomies were performed

In the marginal group, eight patients were delivered spontaneously, four after rupture of the membranes to induce labor and three after the introduction of an intra-ovular bag

65 Cases of Placenta Praevia, 1922-1927
Bellevue Hospital, Second (Cornell) Division

Method of Delivery	Central	Partial	Marginal
Spontaneous	0	0	8
Membranes Ruptured and Spontaneous	0	0	4
Bag and Spontaneous	0	0	3
Bag, Version and Extraction	17	10	4

Forceps	1	0	2
	30	12	23

65 Cases of Placenta Praevia, 1922-1927
Bellevue Hospital, Second (Cornell) Division

	Multipara	Primipara	Maternal Deaths	Infant Deaths	Stillbirths
Central	24	6	5*	8	10
Partial	11	1	0	1	4
Marginal	20	3	0	5	3
	55	10	5	14	17

* 1 due to erysipelas antepartum

Severe hemorrhage occurred in twenty-five cases of which sixteen were central, five partial and four marginal placenta praevias Thirteen of the cases were transfused, two antepartum Gum glucose was used in five cases

Maternal Deaths

Five maternal deaths occurred in the series, all in the central type

Case 1 B V H Admitted May 2, 1922 Para 1 Age 35 Central Placenta Praevia. Delivered by classical cesarean section Died from puerperal infection on the 12th day postpartum

Case 2 A N Admitted April 11, 1925 Para IX Age 42 Central Placenta Praevia Bag

65 Cases of Placenta Praevia, 1922-1927
Bellevue Hospital, Second (Cornell) Division

	Total No Cases	Estimated Blood Loss: To 1000 cc	1000 1500 cc.	1500 cc. plus	Packed	Transfusion: No	Transfusion: Time	Gum Glucose: No	Gum Glucose: Time
Central	30	12	2	16	24	9	7 PP 2 AP	4	2 PP 2 AP
Partial	12	7	0	5	6	2	2 PP	0	
Marginal	23	13	6	4	5	2	2 PP	1	1 PP

Version and extraction 2000 c c saline by hypodermoclysis 250 c c gum glucose intravenously Expelled packing and clots Died immediately

Case 3 A L Admitted June 21, 1926 Para iii Age 24 Central Placenta Praevia Delivered by version and breech extraction 1000 c c saline by hypodermoclysis Bled through packing Died during transfusion

Case 4 A B Admitted February 4, 1927 Para v Age 35 Central Placenta Praevia Bag Version and extraction Packed 450 c c gum glucose Died during transfusion

Case 5 M T Admitted February 11, 1924, to the erysipelas ward with facial erysipelas and a temperature of 102 Entered hospital for vaginal bleeding Vaginal packing was introduced and after its removal a No 4 bag Delivery by version and extraction Uterus was packed There was no difficulty with the delivery and no profuse hemorrhage at this time. The patient died six days later of general infection

Conclusions

As a routine treatment for placenta prævia, the insertion of the extra-ovular bag is the most suitable procedure in the central and partial variety and the intra-ovular bag in the marginal type.

2 The intravenous use of gum glucose to relieve shock temporarily until transfusion can be given, has been helpful and safe.

3 Transfusion is the most valuable means of combating shock and should be used in the treatment of placenta praevia before, during and after the delivery

---

THE TREATMENT OF PSYCHONEUROTICS AND BORDERLINE MENTAL STATES*

BY D C WILSON, M D, CLIFTON SPRINGS, N Y

THE treatment of this class of patients is still in such a chaotic state and varies so with the individual physician, with his environment and education, that it would seem worth while to emphasize a few points that have come to our notice while handling these cases during the last five years So many cases come to the clinic with the diagnosis of one of this group of diseases, yet are found to have none of its characteristics, while so many others enter with such a diagnosis, yet are frank and dangerous psychotics that we are taught again and again that the diagnosis is difficult and that there is still a great deal of misunderstanding In fact, we know that the correct idea of the patient very often cannot be formed until weeks of observation have been utilized and even then, an exact understanding of the case may be impossible The diagnosis of a neurosis has been made 2,639 times at the Clifton Springs Sanitarium and Clinic during the last five years and although such a diagnosis is not made without great care and close observation, follow up shows the report in error in some instances It has been impressed on us especially that we are more apt to underestimate the seriousness and the gravity of the mental disorder A psychoneurosis very often is found to be but the beginning of a well organized psychosis It is not difficult to recognize that a neurosis is present but the prognosis is exceedingly hard to make

A survey of the attitude toward this type of mental disease is very interesting Psychiatrists through the latter part of the Eighteenth century and continuing to the time of Morel in 1850 were looking for unity of cause, course, and outcome in all insanities The concept of vesania or pure insanity covered practically the entire field of so-called mental disorders It is very interesting to note that Cowles in 1885 still held to this term but considered neurasthenia as its initial stage. In this country at least the next development in the history of the psychoneuroses was controlled by the organic neurologist, the somatists (perhaps) or rather those who considered a neurosis as resulting from organic disease namely physical weakness either inborn or acquired Perhaps the influence of Weir Mitchell had a great deal to do with this His "Fat and Blood" and other articles are certainly built around this assumption. This led to the belief that the neuroses were the legitimate property of the organic neurologist, or the internist, who treated them with little regard for their mental mechanism We still feel this influence so that when a diagnosis of neurosis is made, it is considered by some as evidence of ignorance and to be synonymous with the admission of failure to find any somatic cause Such diagnosis by exclusion should be absolutely stamped out and if made it should be insisted that the intrapsychic conflict causing the neurosis be demonstrated Gradually toward the end of the nineteenth and the beginning of the twentieth century a new concept of all mental disease has developed

As far as the psychoneuroses are concerned this change of attitude has been instigated and carried on most enthusiastically by Freud and his disciples His teachings have undoubtedly shed great light on the cause of this class of diseases, their interpretation, and treatment As one dwells among and studies these people one learns to appreciate more and more the Freudian classification, and although not agreeing with his explanation of the etiology of each, yet one must admit

* Read at the Annual Meeting of the Medical Society of the State of New York, at Albany N Y, May 23 1928

the great contribution that has been made By Freud the neuroses are divided into the psychoneurosis and the actual neurosis or those that have a definite organic element In the former group the hysteric is recognized as a form of reaction to a repression by means of a somatic conversion, while the psychasthenia reacts symbolically with fears, phobias, and obsessions The anxiety neurosis, one of the actual neuroses, is founded on the basis of fear, while the neurasthenic has become narcistic and is paralyzed by self worship During the last two decades the interpretation of all mental disease, to a certain degree, has followed Freudian lines Now the mental diseases are considered to arise from intrapsychic conflicts caused by some disagreement of the id, libido, "elan vital", or instinctive drive and the ego or ego ideal, while the form of disorder depends on the type of personality and the severity of the conflict This attitude has put the neuroses definitely in the class of mental disorders showing them to be the most interesting and hopeful field that is open to the psychiatrist

It is perhaps worth while to review a few of the criteria sometimes used to differentiate the neurotic from the psychotic. The former is supposed to have insight, to understand that something is wrong, and to seek outside help, while the psychotic does not realize that anything untoward is happening No such difference exists Many psychotics have complete understanding, even correctly diagnose their own condition, while a clear understanding is the last thing the neurotic often desires It is often stated that a neurotic will never become a psychotic. This is, of course, not true Many psychoses give the history of previous so-called nervous breakdowns The involutional depression case has often had frequent stages of mild depression and acute agitation which simulate neurotic states very closely In the onset of schizophrenia, Sullivan[2] states as follows "The great number of our patients have shown for years before the break clear signs of coming trouble A number of them were brought to notice by the outcropping of behavior of a simple psychoneurotic sort, unwitting attempts at the hysterical incapacitations not only preceded many psychoses but make up much of the psychotic picture in some cases Reactions by obsessive substitutions are seen in a small number to have preceded for years frank schizophrenia, a mingling of doubts and scruples of a simple psychoneurotic nature The graduations from the neurasthenic picture into schizophrenic would be easy to observe, did we but attend more clearly to the mental state of quasi-normal adolescents Anxiety conditions which deepen into schizophrenic panic occur in numbers The psychiatrist sees too many end states and deals professionally with too few of the pre-psychotic" The distinction, therefore, between the two mental mechanisms is often impossible and becomes a distinction almost without a difference Hysteric and schizophrenic reactions, manic states, mild depressions, hallucinations and delusions, ideas of reference, and stupors are found in both classes They are mal-adjustments of the individual of varying degree and kind, depending on the severity of the intrapsychic conflict and reacting strength of the individual "In the psychoneurosis," according to Noyes,[3] "the conflict results in a compromise that neither violates the customs of society nor damages the personality" The problem is to decide whether the personality has been seriously damaged and society outraged There is also another problem which seems to be most important, that is, to decide the accessibility of the intrapsychic conflict The success of treatment hinges on the ability to reach an understanding of the conflict The disease is benign or malignant according to this criterion This fact decides the necessity for a complete and detailed psychoanalysis, the question of committment and institutional care.

Ideas regarding therapy for the pre-psychotic or benign mental are many Most text books of today say the ideal treatment is psychoanalysis, but if this is not practicable the Weir Mitchell treatment should be used A person who is not equipped or does not believe in either method of therapy is left without resource Internists who handle these cases believe firmly that if foci of infection are removed, disorders of the different viscera attended to, and the patient rested, success will follow Yet, it is well known that rest is often absolutely contraindicated. The psychiatrist in private practice who does not devote himself to psychoanalysis, would explain the internist's success as an example of the accessibility of the conflict or would look for a prompt recurrence of the disability What is the psychiatrist to do? He has so many patients, even if trained to do so, he could not analyze completely He also has seen the dire effects of attributing all nervous disorders to sexual causes It is not pleasant to be dwelling constantly in the realm of perversion, or of anal, oral, or genital eroticism He has been warned of the dangers of incomplete analysis The analysist can only handle a very limited number, the rest cure fails, but someone must handle this great mass of suffering individuals A doctor said to me "My mornings are delightful while I make rounds, but the afternoons are terrible. My office is crowded with people who say they are nervous I can't get anywhere with them Can you tell me what to do?" The answer to this problem is found in the fact that in the benign mental case, the conflict is accessible No detailed analysis is necessary, but enough so that the mental mechanism is revealed, can be grasped almost completely if not in entirely, and finally is understood well enough to explain it to the patient while definite and practical plans are instituted to bring about adjustment. This form of partial

analysis is successful and will bring results

Heldt[4] in the Ford Hospital has demonstrated his ability to manage mental diseases in the general hospital He has shown what great benefits follow the simple adjustments It seems to me that the internist who tries to treat these patients is taking a great risk, he has not the time or the training to work out a practical scheme for rehabilitating this form of maladjustment He should not have his office full of nervous patients, he should refer them to a psychiatrist or if this is not possible, take the time to learn that soma and Psyche are one and as the mind is in conflict so is the body, then try to rearrange the abnormalities of thought The psychiatrist on the other hand can recognize after a little study the extent of the conflict and the accessibility of the source of the anti-social trend If the case is too malignant and simple analysis fails, then it should be segregated perhaps for a detailed analysis or for institutional care The neuropsychiatric ward of the general hospital cooperating with a well run, out-patient department offers much in the solution of our mental problems

The ideal form of treatment for the prepsychotic then, depends first, on the understanding that the neuroses are a form of mental disease and are often potentially malignant There is no borderline, between the psychoses and psychoneuroses, one fuses into the other Neuroses should be treated as other forms of mental disease Next, an unbiased view of the patient should be obtained if possible The patient no matter how hard he may try, cannot tell you the complete truth as often they cannot distinguish between truth and imaginings, especially when questioned they will often describe fantasy as fact A relative who gives a slightly different view is of great assistance, while a neighbor is even greater help A clear understanding of the case is most often entirely impossible without this outside aid, it is so easy to suggest one's own thoughts and have the patient pass back the suggestion as an actual experience that one must have some other contact beside the physician—patient relationship A well organized social service of course, is the ideal, but if this is not available, the opinion of the family doctor not as a doctor but as an understanding friend can nearly always be obtained

The status of the physical organism must also be thoroughly investigated, somatic trauma is just as important as psychic and must not be underestimated, calling, as it does, for a close communion between the internist and psychiatrist An anxiety state excited by a diseased gall bladder cannot be cured unless the gall bladder is attended to A neurasthenic reaction in a person poisoned by bad teeth and tonsils is difficult to cure unless the toxic focus is removed The correction of hyperchlorhydria, spastic constipation, poor circulation, and abnormal diets by some simple therapy is often of most vital importance The attitude is frequently taken that a person is too nervous to stand surgical shock such as tonsillectomy or the removal of bad teeth First, the nerves must be strengthened before anything is done There is truth in this and it is a matter for careful judgment depending on the individual case but it seems to me to follow, if there is definite and unquestioned pathology, that final success will be obtained sooner and with much less difficulty if this can be removed before rather than after the attempted adjustment It, however, must be remembered and re-emphasized that neuroses do not develop in a day, that emotional instability such as seen in a neurotic reaction to a diseased state is deep-seated in the personality Therefore, it must not be thought that because organic disease is found, it explains the presence of a neurosis

The next therapeutic step is the development of a chronological history of the patient's life and reactions gradually portraying an understandable picture of the personality and its environment, detailed enough so the physician can understand the conflict and can explain the unhealthy compromise This may take from five to ten conferences of an hour but rarely need be more extensive It is not required of one to delve into infantile fixations, sadistic trends, or other deep-rooted psycho-pathology, a form of research that can be left for the more malignant case which can now be recognized, segregated, and if necessary institutionalized Such deeper studies often cloud the picture in the more accessible cases and while interesting psychologically, prevent a successful outcome

Following this comes the period of regeneration A way out must be found, the instinctive drive liberated, redirected, given new birth, new hope and understanding guidance Reeducation, retraining, and help in overcoming fears must follow These cases cannot be allowed to drift, they need support during convalescence A parole system similar to the one used with the psychotic would be ideal These people could be made reportable to the state mental hygiene commission which in turn could force a constant recheck, but as this is not yet possible they should certainly be made to report from time to time to the analyzing physician or some other that understands their mental mechanisms At each recheck they can again be adjusted, strengthened, and directed until able to control their own responses and to face reality without compromise

I would like to give two cases illustrating a few points in this paper

Case No 8098, a woman of thirty, entered the Sanitarium first on February 7, 1922 She complained of a great deal of pain about the rectum Her father was a clergyman, who gave up his ministry at forty-eight, because of a depressive attack from which he recovered The mother had nervous exhaustion at 42 The patient had

been a very precocious child, very difficult to manage, and stated that she always considered herself superior mentally At the age of 2 she was operated for hemorrhoids, after which she had a temporary loss of vision As the sight returned she began to have pain in the rectum, for which she ran the whole gamut of the medical world, consulting our most famous medical clinics and medical men as well as osteopaths and Christian Scientists At twenty-four she was better and remained so for two years when the pain in the rectum returned forcing her to again seek all kinds of advice and to have many local operations until she was finally put on her feet temporarily again She was treated by means of suggestion for a year and a half until she was able to teach for three years and afterwards serve as a Y W C A secretary for three more At this time she was first in my care complaining of a slight recurrence of her malady from which she promptly recovered

In June, 1927, she returned because of nausea and mucus colitis Complete study showed nothing physically wrong but an achylia and she left apparently improved having been diagnosed a psychoneurosis, hypochondrical type The mental disorder was not investigated further

In December, 1927, she reentered complaining of sleeplessness and was found to be in a schizophrenic panic Several psychiatrists had seen her during this interim but had been unable to help her Analysis at this time was very difficult and entirely unsuccessful but it demonstrated that she had been schizophrenic from the outset as the reactions in early adolescence had undoubtedly been of this character She is now in Bloomingdale The malignancy of this process should have been recognized years before and appropriate therapy instituted, perhaps it would have failed but at least it could have prevented many surgical shocks and osteopathic procedures

The second case is given to illustrate the value of partial analysis

Mrs E W, aged 36, entered January, 1928, complaining of shell shock following many superficial injuries received during a terrific explosion in August, 1926 During the two years she had suffered a great deal from a severe burning pain in the upper left abdomen, had been bed-ridden most of the time, had spells suggesting catatonic stupor, and at times she felt separated from her body, things were unreal and she seemed separated above herself watching her own conduct Up in one corner of the room she had seen almost daily a hideous monster which took on many shapes After some difficulty it was found that during childhood the patient was greatly domineered and imposed upon by her mother causing her to develop definite feelings of inferiority Then at the age of sixteen she had been taught by her lover to assert herself so that she overcompensated and since that time had driven herself without stint and even after marriage continued at high speed pressed on by fear that she would not equal or surpass every rival until she became very successful and the head of a large office Her husband in the meantime stood still, frowned on all advancement, wanted her alone more or less as an idol, and discouraged all social outlets He was a "wet blanket," refused to have children and did not satisfy her sexually She made every effort to cover this up so they appeared to the world a very happy couple although at the time of the accident she had been so unhappy for ten years that she was even contemplating suicide as a method of escape She continued to drive herself at high speed to forget The crash came, a way out was offered, and she went to bed to stay there, of course, with much agonizing and suffering After the story was told the patient was urged to talk the matter over frankly with her husband She delivered an ultimatum after which she stated that she had begun to do what she wanted for the first time in her life She got out of bed and has apparently made a complete recovery This woman had been seen by many physicians and neurologists and I believe could have been cured previously by an investigation of her mental make-up

In conclusion may I emphasize the value of considering these patients as malignant and benign so that their treatment can be varied accordingly and again point out the importance of a practical analysis Other measures such as rest, isolation, change of environment, and physical rehabilitation are important and often essential, but a mental adjustment is necessary for a permanent cure and also this form of psychotherapy is available to every psychiatrist Finally nowhere can such encouraging results be obtained or such terrific suffering prevented as in the treatment of the benign mental, the psychoneurotic, and pre-psychotic states of mind

LUPUS ERYTHEMATOSUS TREATED WITH GOLD AND SODIUM THIOSULPHATE, A REPORT OF THIRTY-TWO CASES*

By HARRY C SAUNDERS, M.D, NEW YORK, N Y

From the Department of Dermatology and Syphilology, New York University Medical College, Service of Dr Howard Fox

GOLD was first used in the treatment of lupus erythematosus in 1913 by Ruete (1) Since that time, numerous workers, notably Martenstein (2), Fried (3), Ullmann (4), Westphalen (5), Throne et al (6), have employed various gold compounds with good results Among these preparations, were gold potassium cyanide, krysolgan (4 amino, 2 auro-thiophenol-carbonic acid), triphal (sodium salt of aurothiobenzimidazol carboxylic acid), and aurophos (sodium gold double salt of aminoarylphosphinic acid and hyposulphuric acid)

Galewsky (7) was the first to employ gold and sodium thiosulphate in this disease, but concluded that it was more dangerous that krysolgan Schamberg and Wright (8) and Whitehouse and Bechet (9) have reported favorably upon its use in twenty-five and thirty cases respectively

The preparation used in this series of cases was gold and sodium thiosulphate Each dose was dissolved in two cc. of distilled water and administered intravenously in all but one case In this, beginning with the fifth, all injections were given intramuscularly at the suggestion of Dr I Apfelberg There were no painful infiltrations

In most of the cases, the initial injection was fifty milligrams and each of the succeeding doses was one hundred, except where a reaction made a reduction advisable In a few of the later cases, the first dose was reduced to twenty-five milligrams, the second made fifty and each of the subsequent, one hundred

Seventeen patients had reactions of which seven were toxic, nine were cutaneous, and one was both

Of the eight toxic reactions, three were severe, five were mild The former consisted of chills, fever, and prostration lasting from one to two weeks The latter was manifested by slight chilliness and fever in three instances, while in the other two nausea followed directly after the injections

Of those having skin reactions, two complained of generalized itching, one developed itching and angioneurotic oedema of the lips, tongue and throat, one had itching, a local reaction, and a stomatitis, one had a vesicular dermatitis, one suffered a severe local reaction with a generalized urticaria, three had a purely local reaction The local reactions consisted of increased redness and extension of the lesions In three of the patients these local reactions subsided and improvement in the disease followed, in one, the process remained aggravated One patient did not return for observation

There were thirty-two patients treated with gold and sodium thiosulphate in this series Sixteen were males, sixteen females Thirty were white, two colored The ages ranged from twenty-one to fifty-two, the average being thirty-six

The duration of the disease varied from seven months to eighteen years The average length was about two and one quarter years Thirty were cases of the discoid type, one was discoid and disseminated combined, and one was of the seborrhea-like variety In all cases, some portion of the face was involved In seven the mucous membrane was affected Eleven showed scalp lesions and two had patches on the body and extremities

In the cases (1-26 inclusive) in which the patient continued treatment sufficiently long to allow one to draw conclusions, the greatest number of doses given was seventy-six, the smallest two, the average being twenty The largest amount of the chemical used was sixty-five hundred milligrams, the smallest one hundred fifty milligrams

Of the patients treated fifteen were clinically cured, four were almost cured, six were improved and one was not as well as when treatment was instituted Six discontinued treatment before results could reasonably be expected

Conclusions In gold and sodium sulphate, we and efficient therapeutic agent

The first dose should be twenty-five milligrams or less It should then be increased gradually to a maximum of one hundred

It can be introduced intramuscularly with good results and without discomfort to the patient.

Contrary to the finding of Throne et al, (6) we found that the duration of the disease and the extent of the process did not have a direct bearing on the response to treatment. This seems rather to depend on the susceptability of the patient to gold

FURTHER OBSERVATIONS ON CISTERNAL (SUB OCCIPITAL) PUNCTURE*

By LEO SPIEGAL, M D, NEW YORK, N Y

VERIFYING the findings and agreeing with the German and other observers as to the distinct advantages of cisternal puncture over that of lumbar puncture, I have completely discarded the latter for a routine diagnostic test at both the Lenox Hill Hospital and at the University and Bellevue Medical College Therefore today, in all patients requiring either a diagnostic test or where therapeutic measures are indicated, the sub-occipital route is selected as preferable

In a previous article, the technic of the Esskuchen method was described. It is the purpose of this paper to note any unusual incident met with in the 350 punctures so far performed and to discuss the number of failures encountered and ascertain if possible the reasons therefor

Most failures occurred in our experience, when the technic was not as advanced as it is today, and when I was still using an improperly pointed needle of heavy gauge, which caused more trauma and resulted in some discomfort to the patients If the puncture is performed correctly, there is practically no pain or discomfort and patients do not object to a subsequent puncture

It is only in those cases where one deviates from the middle line that pain is complained of or where the angle of insertion of the needle has not been a correct one and where one penetrates too far within the cisternal cavity

Pain in the lower part of the face has happened twice and is due to irritation of the posterior or sensory root of the fifth nerve. This pain, in both cases, disappeared within 24 hours Pain in the arm occurred early in my series and is due to irritation of the first cervical nerve when one deviates from the midline

In a very small number of cases (7), an "electric shock" was experienced by the patient as the dura was punctured This sensation lasts but a fraction of a second and is not due to any faulty technic.

Blood Tinged Fluid—Blood in the fluid is very seldom met with and when it does occur to any appreciable amount, is due to trauma to the venous plexuses at the base of the occiput. When this happens, one must take a fresh needle and insert at a slightly different angle This has happened twice in my series of cases

The first five to ten drops of the cisternal fluid should be discarded as it may contain a few red cells which is inevitable and not due to a technical error Blood in the fluid may also be the result of having an improperly pointed needle, so that the tissues are either lacerated or torn It is most important to have a properly pointed instrument, the care of which will be presently described

Failure to Obtain Fluid—This is due in nearly every instance to having the patient in an improper position, i e, the parts are not in alignment so that the head tilts more or less to one side, thus causing the needle to take an incorrect direction and not reach the dura

Bony deformities of this region, either anomalies of the bone, or arthritic changes have prevented me in two cases from entering the cisterna In one case, four different attempts failed These bony deformities are mentioned by Nonne, Von Sarbo and others Von Sarbo reports that he failed 16 times in 180 punctures

Scars on the back of the neck very often increase the difficulty of puncture but in all of my cases except one, I have been able either to go through this scar tissue or push it aside as the needle was introduced

Low pressure within the meninges may result in a 'dry tap" or yield only a very small quantity of fluid This low pressure, noted also by Jannossy and Saunders, was encountered by the writer on three different occasions and the cause of the failure substantiated by a lumbar puncture which was made at the same time showing a similar low pressure and yielding very little fluid Fluid may run very slowly if the lumen of the needle is not entirely within the cisterna, this is usually corrected by slowly and carefully turning the needle

Headaches of a severe nature occurred in one case and lasted 24 hours, but did not prevent the patient from continuing work Stiffness in the back of the neck is the one symptom most often complained of but never lasts more than a few hours, except in one neurotic individual who complained of discomfort for three days

Great stress should be laid on having a properly pointed needle It is my custom to resharpen every new needle and retouch every needle point before it is again sterilized for future use In sharpening the needle point, I endeavor as near as possible to attain a conical point like that of a cambric needle This is best accomplished by using a carborundum stone and finishing or polishing with an Arkansas oil stone A hand magnifying glass is of great value in insuring accuracy in this work A needle thus prepared, penetrates the dense fibrous tissues much more readily than one with a flat bevel cutting edge as has been shown by Green

In performing the puncture one must feel his way, and at no time guess or use force in endeavoring to reach the cisterna The point of orientation must be felt, and from there on to the dura, the needle must be advanced from ½ cm to 1 cm

* Read at the Annual Meeting of the Medical Society of the State of New York, at Albany N Y May 23 1928.

LEADING OR BEING LED

Medical progress is founded on criticism that is constructive. Anyone can indulge in destructive criticism, for practice never approaches the ideal perfection of the plan The constructive critic may deal destructively with the past, but the destructive critic deals harshly with the future as well as the past

Medicine has its pessimists as well as its optimists, but a great deal of the pessimism is simply inertia or resistance to change The practice of preventive medicine requires group action on the part of both the physicians and the people,—that is, by medical societies, and by groups of laymen, either official or voluntary Many doctors in their intense individualism have difficulty in comprehending the significance of group action, and they see only its possible menace to their personal freedom of action. These destructive critics must be led or even dragged into cooperation with health forces outside the medical profession Physicians are rapidly reaching the parting of the ways where they must decide between two roads, to one to leadership in all forms of the practice of medicine including medical administration, and the other road to the subordination of physicians to lay groups as hirelings in the practice of preventive medicine

The constructive critic proposes two measures for the mutual benefit of themselves and the public

1 Group action.

2 Individual practice of preventive medicine and public health

It seems to be necessary that group action by physicians should come first in point of time in order to educate and inspire individual doctors to enter the preventive field which at present offers but little financial return as compared with the practice of the strictly curative forms of medicine and surgery It is but natural that the public should estimate the cure of an actual sickness to be ten times as valuable as the prevention of a condition only vaguely threatened. But the ultimate objective of all lay groups is to get every person to consult his doctor on matters of personal hygiene or disease prevention, as well as the cure of established sickness Two examples of this objective may be cited,—the first that of hookworm prevention, which has been accepted as standard practice by both the physicians and the people of the Southern states through the efforts of the Rockefeller Foundation.

The second example of the evolution of group action into individual practice is that of diphtheria immunization, the ideal of which is that every child shall be immunized during infancy by the family doctor

The high cost of medical care as practiced by the individual doctor is no longer being discussed by health agencies alone Business, industry, life insurance are taking an active interest in it. Medicine, itself, is working on the problem But, many physicians have not kept their minds fully open to the change in the world ideas in regard to medical service. Just as business interests grow, so do new conditions arise. Just as public health knowledge increases and the people learn that it pays to have health, and that they can get it, they will not be particular under whose direction it comes

The surprising awakening in industry, life insurance, general business, and corporations in providing medical care to their employees by their own salaried doctors, should awaken practicing physicians to find out where they stand on these public questions, and what their relationship shall be to all the new responsibilities of which the people are talking

So far as preventive medicine is concerned, the medical profession will have to adopt as liberal a policy, as the world has adopted in other lines of experience The medical profession may either lead in solving these medical problems, or it may be led to follow a policy that others will call reactionary conservatism

There is a new era in public understanding not only in public health, but in that which constitutes good methods of practice We all recognize the public's understanding of good practice, but the public's understanding of public health needs and the position of the health agencies in it are not quite realized by many of us

The present organized lay health activity reflects basic conditions in public demand more accurately and dependable than individual opinion does The activities of organized medicine reflect more accurately professional attitude than individual opinion does The present activity in health conservation is the result of a public demand that has been growing for some time, yet so gradually that the medical profession in its zeal for scientific medical advance and the maintenance of a proper economic reward has not everywhere realized its advance. Doctors will change just as fast as they realize the situation; and they will abandon the old individualistic attitude and ideals and will adopt those of cooperating methods and leadership in all public health movements

The history of organized medicine in this state as shown by the recorded history of its yearly meetings indicates that a statesmanlike attitude toward public health agencies will be taken, and that we may look forward to a new set of ideals that may be far in advance of the past.

THE AMERICAN MEDICAL ASSOCIATION

The annual meeting of the American Medical Association held on July 8-12 in Portland, Oregon, was too large and too varied to be reported properly in this JOURNAL The description of the meeting printed on page 955 of this JOURNAL is only an impression of the formal actions taken by the House of Delegates The representatives from New York report that the sessions were of unusual value and that the arrangements for their comfort and entertainment were faultless

MEDICAL PROGRESS

Rheumatic Infection.—Professor W H Veil, internist of the Jena University clinic, sums up his serial article as follows he believes that we can obtain a better comprehension of certain local affections—cardiac, renal, and chronic arthritic—by regarding them as manifestations of rheumatism The treatment of the latter is a matter of overcoming unusual resistance. The author alludes to the doctrine of oral infection which is attended by a high degree of resistance The latter term he uses to connote the vast pains which the internist must take to incriminate or exclude oral infection It may happen that a patient with a puzzling case of rheumatism is just then rejoicing in the possession of new crown and bridge work, which is not only a work of art, but represents an investment of a large sum of money The outcome will depend on the character of the rontgenograms, how they were taken and by whom interpreted For the physician to order the work undone is a severe strain on him, to say nothing of the attitude of the patient This is what the author means by overcoming resistance in regard to the dilemma which must arise in such cases The trouble is not solved by removal of the prosthesis, for extraction of roots may have to be done by the open method in order to make sure of drainage, and of radical removal of infectious foci Again other possible foci, such as the tonsils and nasal sinuses, cannot be neglected In certain cases there is a direct connection apparent between infected tonsils and myocarditis with heart block in which tonsillectomy gives prompt relief, as in a case cited by the author Of medical remedies the author recommends intravenous injection of the patient's own blood, and drugs of the salicylic group and its derivatives—*Deutsche medizinische Wochenschrift*, April 19, 1929

Some Ophthalmic Emergencies in General Practice.—A Maitland Ramsay considers three outstanding examples of the types of ophthalmic emergencies that the general practitioner may be called upon to deal with, namely, (1) injury to the eye of a child, (2) acute glaucoma, and (3) sudden blindness in one eye In connection with the first of these it should be remembered that the fate of the eye will depend upon its treatment during the first twenty-four hours The physician's first duty is to inquire fully into the history of the accident. While he is doing this, the child should be laid on its back in a good light and told to keep both eyes shut A few drops of cocaine placed at the inner canthus will soon anesthetize the eyeball, though possibly a general anesthetic will be needed to make the examination There should be no unnecessary manipulation and no copious douching A 10 per cent solution of argyrol may be used freely, and if there be a prolapse of the iris toward the center of the cornea, 1 per cent atropine should be instilled The general practitioner should never attempt to excise a prolapsed iris The eyelids and side of the face should be painted with iodine, a compress and bandage applied, and the patient put to bed until the specialist arrives (2) There is danger that the nausea, feverishness, retching and vomiting associated with acute glaucoma may be mistaken for a bilious attack. In a case with these symptoms, biliousness or migraine should never be considered until it is certain that there is nothing wrong with the eyes In acute glaucoma morphine is invaluable To contract the pupils and reduce the tension, eserine in 1 per cent solution should be employed The bowels should be moved freely with calomel followed by a saline draught. Sleep should be secured and operation should not be delayed Glaucoma must not be confused with iritis, in the latter the vigorous use of atropine is imperative, but a mydriatic will gravely aggravate the symptoms of glaucoma. (3) In case of sudden blindness in one eye it is important that the general practitioner be able to make an ophthalmic examination, as this will enable him to place the patients in one of three groups (1) The whole field of vision is lost, (2) central vision is lost, but peripheral vision is preserved, (3) the defect is in the peripheral field of vision, but central vision is retained in whole or in part This knowledge will very quickly make it possible to arrive at a definite diagnosis—*The Practitioner*, April, 1929, cxxii, 4

Black Dermographism.—White and red dermographism are familiar induced phenomena, but even the possibility of a black variant would have been scouted had not two Russian observers, Emdin and Kusmenko, stumbled upon this manifestation in 1923 Two years later the case was published and Professor M Breitmann of Leningrad brings the subject before the general profession It was thought at first to occur only in hysterical subjects, but it cannot be rare because the author has seen over a hundred cases since 1927 and of this material not one patient could be classed as

MEDICAL SURVEYS

A medical survey of a county such as that of Jefferson County, published on page 959 of this Journal reveals a surprising number of contacts of practicing physicians with lay organizations engaged in public health work It is probable that the report will enlighten the physicians of Jefferson County quite as much as it will those of the rest of the State, the report should encourage Jefferson County practitioners to know that they rank high in the performance of their civic duties along public health lines

---

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO

Pure Food and Drug Bill Twenty-five years ago the Senate of the United States discussed a Pure Food and Drug Bill which was opposed by manufacturers of proprietary articles This JOURNAL of August 1904 contains the following comments quoted from the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

"If there was ever a question before the national legislature in which the medical profession should be interested it is the Pure Food bill, now before the United States Senate

"The hearings on this measure before the Senate Committee on Manufactures revealed some very interesting facts Thus the attempt made in the bill to establish the United States Pharmacopœia as the standard of purity for drugs was combated by the proprietary medicine men with the representation that the United States Pharmacopœia was published only every ten years, that many new preparations, on which it was necessarily silent, came into use during each decennial interim and that, consequently, the United States Pharmacopœia could not be made available as a standard It was but natural that the strictly sordid commercial interests should turn fiercely against the entire measure The proprietary medicine trust was deeply if not vitally interested It dropped its policy of direct representations to the committee and took recourse to its customers, the retail druggists, who, scattered all over the country, have been instigated to write letters and send telegrams to their respective Senators protesting against the passage of the bill The pressure in this instance is that of credit, which the large manufacturing concerns are in position to extend or not to their patrons, who, by counter prescribing, vend these dangerous nostrums directly to the public

"When the Senate committee suggested that these formulæ ought to be published, or at least registered, and that it would be only fair to hold the manufacturers to their own standards, the objection was urged—the startling admission was made—that such a course would be ruinous to the large commercial interests involved It thus becomes apparent that, in prescribing unofficial preparations physicians are very liable to be prescribing only a name with no guarantee that that name stands for anything definite either in number, quantity or quality of ingredients Facts of this kind have long been known or at least surmised by physicians, and their confidence in modern pharmacy has been almost shattered

"Beside the proprietary medicine concerns, there are the vast commercial interests involved in food adulteration, and the opposition from this source and from the still more active hostility of the liquor interests working in behalf of compounded and blended drinks under various names has supported a powerful lobby ever since the beginning of the consideration of the bill

"The duty of the medical profession at this juncture is obvious Every physician should bring his utmost influence to bear on the question Whether he is a committeeman appointed for the purpose or not, he ought at once to write the strongest possible letter to each of his United States Senators, he ought to get others, both within and without the profession, to do likewise, and especially ought he to get his druggist to cooperate The influence of the physicians in a community on the druggist ought to be at least equal to that of the patent and proprietary medicine men"

when contrasted with his present excellent condition including the disappearance of all symptoms makes it unusual (with the one exception that the blood pressure remains high, indicating that certain organic changes in the vessels are irremediable) The numerous distressing symptoms then could not have been due merely to hypertension but to the toxin causing the same.—*Münchener medizinische Wochenschrift*, April 19, 1929

A Case of Intestinal Type of Hodgkin's Disease.—Z V Oglobina describes a case of a rare form of intestinal lymphogranulomatosis in a woman, aged 43, who had been ill for four months, and in whom a diagnosis of intestinal carcinoma had been made She had occasionally suffered from nausea, eructation, and diarrhea, and lately from constipation, and had lost 16 pounds in weight She was operated upon because of symptoms of stenosis of the small intestine A segment of the small intestine, 138 centimeters in length, was resected, along which were discovered four circular tumors, and immense glands were found in the mesentery There was considerable improvement during a period of eight months, when she again suffered from abdominal pain, weakness, and night perspiration She died with symptoms of peritonitis Autopsy revealed a perforated ulcer of the duodenum, multiple ulcers of the small intestine, and an affection of the kidneys Microscopic sections of the tumors removed at operation showed the structure of granuloma malignum In the literature the author has been able to find only 28 cases of this type of granuloma malignum In 16 of these, operation was performed, but in none of them had the correct diagnosis been made before operation. It is difficult to differentiate the disease from intestinal tuberculosis, cancer of the stomach or malignant growth in the intestines, as the local symptoms of the three diseases are similar The physician has to rely upon general signs characteristic of lymphogranulomatosis, namely, rise of temperature, pruritus, abundant sweats, and eosinophilia The prognosis is very grave—*Acta Chirurgica Scandinavica*, lxiv, 6, 1929

Treatment of Chronic Otorrhea with Calot's Solution.—I. Harmick, writing in the *Canadian Medical Association Journal*, May, 1929, xx, 5, shows that chronic infection, excessive formation of granulations, ostitis, and tubal disturbances are the leading factors in the maintenance of a chronic aural discharge The aim of any therapeutic agent must therefore be directed toward the removal of these causes which maintain the otorrhea Perhaps Calot's mixture is the best medicament ever employed for this purpose Its composition is as follows Guaiacol 10 gm, creosote 50 gm, sulphuric ether 300 gm, iodoform 100 gm, olive oil 700 gm After carefully shaking the bottle, five to ten drops of the solution are instilled into the canal of the affected ear In order to get the fluid into the eustachian tube tragus massage is employed This procedure is carried out every night for a week, when the secretion will have changed from a thick, ropy to a thin, serous nature. When it is also markedly reduced in amount, the instillations are discontinued, and insufflations of boric acid powder or zinc oxide are used At time surgical intervention is necessary before Calot's solution will become effective in clearing the otorrhea This solution should be tried in cases of chronic ostitis before deciding on the radical mastoid operation Most cases of otorrhea, not due to cholesteatoma, and not on the basis of lues, diabetes, local malignancy, or actinomycosis, respond readily to its use In a series of 68 cases, which the author analyzes, by far the larger number were effectively cured by the use of Cabot's solution.

The Local Treatment of Acne—Paul Blum and Jean Meyer refer to the unsatisfactory character of the treatment of acne, for even such remedies as give relief at first may later prove ineffective or cause reactions when pushed too hard. They discuss two comparatively recent resources which, with the aid of diet and hygiene and the casual use of surgical and other local measures, give results superior to the average. The first of these is the bacteriophage, directed against the pustular form of the disease. Each pustule must be punctured with the tip of a vaccination stylet, the pus expressed, and the remedy injected into the cavity with a fine needle Parenchymatous injections may also be made into the base of the pustules and the interpustular area may be scarified and the bacteriophage rubbed in A slight local reaction ensues and on the following day improvement usually occurs The bacteriophage used is evidently polyvalent. The authors are unable to explain this curative activity, which may or may not be specific The other resource, the ultraviolet ray, is not new, but there have been improvements in technique The mechanism of action is double—bactericidal and exfoliative The methods used for determining in advance the proper dosage and for applying the treatment are too detailed for quoting One application of what the authors term the purpuric dose, causing a marked reaction and desquamation, has been known to clear up an area of comedones and papulopustules completely At the same time the authors mention the need of many sessions to cure some patients.—*Le Bulletin Médical*, April 24-7, 1929

hysterical In seeking for a common denominator the author found one in endocrine disturbances Many of the patients were women with hyperthyroidism and with the progress of the disease toward amelioration, the phenomenon grew less marked, vanished and could not be induced again when the patients were seen later In some auscultation cases the ring of the stethoscope left a black mark. A colleague, F S Jurjew, has noted the phenomenon equally in dystrophia adiposogenitalis but the author found most of these patients negative Other endocrine conditions are not mentioned by name In speculating on the nature of this phenomenon the author is able to exclude the possibility of foreign material on the surface Face powder in fact seems to prevent the manifestation All possible coloring matter in the skin or blood has been under consideration, especially sulphur and its derivatives, but no advance has been made in throwing light on the production of the phenomenon The action of the sweat or of any substance contained therein can be excluded The phenomenon may be elicited deliberately by a regular technique or may appear in the course of other manipulations, as in percussion and auscultation While the white and red forms of dermographism are readily understood as manifestations of vasoconstriction and vasodilatation, it is evident that no such simple mechanisms can underlie the black form which will require intensive study before its causation is learned.—*Münchener medizinische Wochenschrift,* April 12, 1929

The Scarlet Fever Problem.—Professor F von Gröer of Lemberg concludes that the Dick theory of scarlet fever is in need of revision The Dick toxin is to be comprehended as an allergen and the Dick test as an allergic reaction, while the Dick immune bodies cannot be regarded as an antitoxin The action of the serum and the extinction phenomenon cannot be regarded as a mere activity of the latter The properties and the mechanism of action of the Dick antibodies must be carefully studied The pathogenesis of the disease is therefore not to be explained by the assumption of the dominance of hemolytic streptococci in the etiology The secondary toxic theory has at the moment the best outlook for a fruitful working hypothesis From the practical angle serum therapy is of the greatest significance, for the diagnostic test is untrustworthy Prophylactic action of the serum is not yet assured beyond all doubt and its use for this purpose must be further developed and better grounded Professor U Friedmann, who has been accused by von Gröer as upholding the views of Dick throughout, expresses himself in a succeeding article as misrepresented He has considered both claims, pro and con, side by side He differs with von Gröer on several points First the Dick toxin does not behave like a local allergen in some respects, although so doing in others There is resemblance without identity Von Gröer holds that every true toxin must behave like the toxins of tetanus and diphtheria This antiquated view has surely been superseded in our present knowledge of toxins Certain aspects of the Dick theory which von Gröer regards as disproved are in the author's opinion still open questions The controversy brings home to the reader the intricacy of the problem and the abundant opportunity for conflicting experience and interpretation Friedmann prefers to leave almost the entire problem as unsolved and refuses to sum up any individual opinions —*Klinische Wochenschrift,* April 25, 1929

The Relief of Toxicosis Apparently Due to Animal Protein.—This question is answered at great length by Dr Bienstock of Mülhausen from experiments made upon himself He is now 68 years old, of sound stock and free from any suspicion of alcoholic, nicotine, or syphilitic influence Typhoid fever in 1883 was followed by acute nephritis in 1884, resulting from a peritonsillar abscess From this he appeared to have made a complete recovery In 1889 he had attacks of renal colic and these have recurred nearly to date He went through pneumonia twice during 1909 and 1910 with a third attack in 1918 These attacks seem to have been determined by exposure In 1922 he found by chance that he had a blood pressure of 160 He then complained of attacks of teichopsia, short breath on exertion, flushed face, attacks of rhinitis of a peculiar type with blocking of the nasal passages and resulting poor sleep Other symptoms were nycturia, various paresthesiae, exhaustion and rush of blood to the head His blood pressure continued to increase to 200 and more The urine and the heart finds were negative to ordinary tests although after various dilution and concentration tests it was thought possible that the first stage of contracting kidneys was present. None of the usual measures brought down the tension, but the symptoms improved when animal protein was eliminated from the diet The author then naturally began to accuse intoxication by animal protein acting as an allergen No attempt seems to have been made to isolate any special protein and the author has eschewed even milk, eggs, and cheese Professor Stahelin who had charge of the patient thinks the case well worthy of publication, for the age of the subject with his history of various ailments

LEGAL

By Lloyd Paul Stryker, Esq
Counsel, Medical Society of the State of New York

CRIMINAL LAW—COMPELLING ATTENDANCE OF WITNESSES OUTSIDE THE STATE

In a civil litigation a party desiring to obtain the testimony of a witness who is outside the state, cannot compel the personal appearance of such witness on the trial of the action It frequently happens that witnesses outside the state voluntarily appear and give testimony for one side or the other But even if they refused to do so, the party desiring their testimony can, under the statutes of New York State, take their deposition in the state in which they reside either by the attorneys for both sides going to the place of residence of the witness and there taking his deposition or, can be done by both sides preparing written interrogatories to be propounded to the witness by a notary public of the state in which the witness resides The deposition so taken may be used on the trial of the action by either party with the same force and effect as though the witness had personally appeared and testified

In a criminal case, however, a different situation presents itself Our statutes give the defendant in a criminal case the right to take and use on the trial the deposition of a material witness who resides in another state in exactly the same manner as in a civil case, but the same privilege is not accorded to the district attorney prosecuting a criminal action The district attorney cannot use in the trial of a criminal case any deposition of a material witness taken outside the state, for the reason that the defendant in a criminal case has a constitutional right at the trial to see every witness who is there produced against him The defendant's right in this respect is called the *right of confrontation,* and under our statutes it is regarded as a part of the defendant's right to due process of law It is obvious that the administration of the criminal law is seriously hampered unless the district attorney has some means of compelling the attendance of a material witness outside the state We are all familiar with the numerous instances where material witnesses for the prosecution in a criminal case have deliberately absented themselves from the state until the termination of the trial and thus the guilty have often escaped punishment In New York we have attempted to remedy this situation, but the statute governing the point involved presents serious limitations

Section 618a of the Code of Criminal Procedure provides as follows

"If a judge of a court of record in any state or country bordering on this state which by its laws has made provision for commanding persons within its borders to attend and testify in criminal actions in this state, certifies under the seal of such court that there is a criminal action pending in such court, wherein the defendant is charged with a crime of the grade of a felony, and that a person residing or being within this state is believed to be a material and necessary witness in such action, a judge of a court of record in this state, upon the presentation of such certificate and such proof of the materiality and necessity of such witness as he may require, opportunity being given such witness to appear before such judge and be heard in opposition thereto, and upon request so to do by the clerk of the court issuing such certificate, shall issue and attach to such certificates a subpoena commanding such witness to appear and testify in the court where such criminal action is pending at the time and place to be stated therein If any person on whom such subpoena has been served in the manner provided by this chapter, having been tendered by the party asking for the subpoena the sum of ten cents for each mile to be travelled to and from such court, and the sum of five dollars for each day that his attendance is required, the number of days to be specified in the subpoena shall unreasonably neglect to attend and testify at such court, he shall be punished in the manner provided for the punishment of disobedience of any other subpoena issued from a clerk of a court of record in this state, provided, however, that the laws of the state or country in which the trial is to be held gives to persons coming in the state or country under such subpoena, protection from the service of papers and arrest"

The obvious limitations set by the statute above quoted to the compelling of the attendance of witnesses outside the state on behalf of the prosecution, is among other things a subject-matter of an extremely interesting and well considered paper by George Z Medalie of the New York Bar, published in *The Panel,* a monthly publication of the Association of Grand Jurors of New York County, entitled Inter-State Exchange of Witnesses in Criminal Cases" As Mr Medalie points out, there is no good reason why the statute should be limited in its application to bordering states The laws concerning the use of

Regional Vaccination at the Port of Entry —P Poencloux reports a new method of curative immunization upon which he has been at work for several years It consists in the injection of vaccines beneath the infected mucosae He appears to have worked chiefly in the mucous membranes of the urogenital tract and to have employed vaccines against the gonococcus, coli bacillus, staphylococcus, and streptococcus The site for the injection is the port of entry of the bacterium In the case of gonorrhea in the male this is the urogenital orifice and the author by means of a small syringe and fine needle makes his injection beneath the mucosa of the meatus after having produced intraspinal analgesia In urethral gonorrhea in the female the latter is not required, for one can throw a little vaccine directly into Skene's ducts Only in a small minority of cases does the disease originate at the opening of the vulvovaginal gland ducts or at the os uteri These injections have a diagnostic value as well, for if no reaction develops *in situ* we know that we have selected the wrong vaccine, based on error of diagnosis If the latter has been correctly made the reaction occurs *in situ* in 30 to 45 minutes, and may be quite sharp with chills and temperature rise Whether this reaction is weak or strong the symptoms improve not only locally but in all of the metastases, but this improvement is short-lived and must be followed up by further injections, every 2, 3, or 4 days

In cases of failure we should think of the likelihood of a superinfection Thus in salpingitis there is sometimes a mixed gonococcus-coli infection in the tubes In such a case a mixed vaccine is substituted, but the author admits that such a resource not infrequently fails, whatever the reason may be In the male the author finds gonococcic epididymitis a good test for his treatment and he has reduced the average duration of treatment from nearly three weeks to one week —*Bulletin de l'Académie de Médecine,* April 23, 1929

Wandering Phlebitis —M Lipschitz states that the first case of this affection, placed on record by E Neisser in 1903, was of syphilitic nature, but that the subsequent material soon showed that syphilis was not the inevitable or even the usual cause The author adds to the histories on record a non-syphilitic case The patient was a man of 49 whose lesion developed a year after an accident to the right leg and lumbar region, after which the parts became swollen and livid History and examination were negative so far as the gathering of further data was concerned, the provisional diagnosis had been sciatica The author to whom the case was referred recognized the presence of phlebitis The case having ended fatally, autopsy revealed that the thrombophlebitis had originally appeared in the right iliac vein, apparently following the contusion in the lumbar region, which had been severe enough to damage the venous endothelium. The interval of a year was an illusion, as the disease process once begun had continued progressively From this moment it tended to appear in other veins of the body, but not continuously, for extensive segments of veins remained intact Death had been due to the formation of thrombi in the cranial cavity There was probably superadded an infection with a germ of low virulence, the chief evidence being an enlarged spleen Blood cultures however, proved negative There were contributory factors in lesions of the coronary arteries and hyperinosis of the blood Buerger of New York has seen numerous cases of migratory thrombophlebitis, invariably in Jews and of unknown mechanism and causation —*Deutsche medizinische Wochenschrift,* May 3, 1929

Vitamin A as an Anti-Infective Agent.— Last year E Mellanby and H N Green published an account of experimental investigations which indicated that an important function of vitamin A was to raise resistance to bacterial infection, and suggested that a deficiency of vitamin A in the body might play an important part in the etiology of puerperal sepsis They have sought evidence on this point by studying puerperal cases of hemolytic streptococcal septicemia Of 24 patients not receiving vitamin A treatment, 22 died, giving a mortality of 92 percent Among 5 patients receiving vitamin A treatment there were no deaths, and recovery was complete in every instance It seems that the effect of vitamin A is rather to increase gradually the general resistance than to act suddenly as might be expected in a substance exerting a specific bactericidal or antitoxic effect The blood cultures in all cases became sterile in about a fortnight after beginning the treatment Vitamin A was administered in the form of two preparations, one of which was about 10 times, and the other about 150 times, as rich in vitamin A as cod-liver oil While these experiments are too few to warrant the deduction that this treatment is specific in its nature for septicemia, they do warrant the belief that vitamin A plays a part as an anti-infective agent to bacterial infection There is no reason to believe that this anti-infective action, if established clinically, would be of importance only in streptococcic infection It is desirable that clinical trials should be made in other bacterial infections The study further suggests that vitamin A must also be of inestimable value in its prophylactic action —*British Medical Journal,* June 1, 1929, 3569

NEWS NOTES

AMERICAN MEDICAL ASSOCIATION MEETING

The annual meeting of the American Medical Association was held during the five days, July 8 to 12, in Portland, Oregon Dr. O S Wightman, the editor-in-chief, of this JOURNAL, and Dr W H Ross, President-elect of the Medical Society of the State of New York, both of whom attended the meeting, united in praising the *Morning Oregonian* of July 9 for its full and accurate description of the meeting Since the items are exceptionally well written, quotations from them will probably set forth the proceedings more accurately and vividly than more formal reports

The proceedings were summed up in the openings paragraphs of the news column as follows

"Members of the American Medical association who are gathered in Portland by thousands from the far hamlets and cities—10,000 strong, including the women and children—began the five-day meeting with loud huzzahs yesterday by crowding upon the battlements of the organization and firing down with howitzers, flameballs, rifles and hand grenades on those from the surrounding population who are trying to break through the stout walls of professional ethics

The ban against advertising by doctors, the ostracism of the physician who prescribes for another physician's patient behind "the other's back," and the many related niceties of ethics will be defended to the last shell

The first event described was the address of Dr William S Thayer of Baltimore, Md, President of the Association, who elicited the surprise and wonder of the reporter by saying what all doctors know, but which the laity have not yet learned

"As a matter of fact, nine-tenths of the good done by the medical practitioner is not from any medicine prescribed We have very few specific drugs The physician studies the case and tells the patient what he ought to do and ought not to do He shows the patient that a red flag is not a smashup"

Dr Thayer was also quoted as saying

"Out of 1,000 medical advertisements 999 are misleading Do not misunderstand me There is nothing immoral about advertising itself, but in the case of the conscientious physician it is suicidal Such a physician cannot compete with the man without conscience when it comes to advertising He cannot promise so much"

The newspaper then applied Dr Thayer's remarks to the concrete case of Dr Louis E Schmidt, who was expelled from the Chicago Medical Society a short time ago and now made an appeal to the American Medical Association for reinstatement after his appeal to the Illinois Medical Society had been denied The *Oregonian* said

"Dr Schmidt traveled all the way out here to appeal from the decision of the Chicago Medical Society, which ousted him for being associated with the Public Health Institute of Chicago—an advertising organization—in that he receives from it $12,000 a year for handling its charity patients The institute is operated by a group of the most influential citizens of Chicago, including Harold McCormick and others of his standing The Illinois metropolis is all upset about the whole affair

"Anyhow, the Illinois society upheld the Chicago society in a decision four weeks ago, and now Dr Schmidt wants action from the national. The matter was taken up secretly Sunday at a meeting of the judicial council, and that is as far as the doctor will get at this session"

The practice of medicine by corporations came up for criticism as follows

"Then at the meeting of the house yesterday morning Dr William A Pusey of Chicago submitted a motion on the same general subject, but much broadened, which was considered so charged with dynamite that even Dr Pusey included the provision that it be considered in special executive session rather than before the house at large

"The motion points out that a year ago the association voted that the practice of medicine was not the proper function of corporations and that the American Medical Association should try to stop such practice Dr Pusey then maintains that there is a growing tendency for organizations controlled by laymen to enter into medical practice He asks

"That the judicial council of the American Medical Association be asked to present to the session at the meeting of 1930 a comprehensive statement for the guidance of the association concerning the practice of medicine by corporations, by clinics, by philanthropic organizations, by industrial organizations, by demonstrations and by similar organizations"

The Red Cross was criticized according to the following paragraph

depositions in civil cases prescribe no such limitation It is also apparent that the proper administration of the criminal law is hampered by the limitation in the statute that the crime charged must be a felony Many criminal charges against public officials may only be misdemeanors, but they nevertheless may be and generally are of such public importance that the prosecution should not be thwarted by technical considerations

Mr Medalie makes another point which is well taken The statute should provide for adequate witness fees, traveling expenses and compensation for the number of days consumed by the witness, and thus the inconvenience that occasionally arises from attendance in a more distant state would, to a great extent, be overcome. Mr Medalie's recommendations with respect to existing statutes on the subject-matter under consideration are worthy of thought and reflection He says

"If all the states genuinely wish to aid each other in the enforcement of the criminal law, it would be an excellent thing if there were held (1) a conference of the representatives of the states, first of the neighboring states and later of all the states, for the purpose of adopting uniform statutes which would assure the utmost cooperation among them, so that no state would receive less than it gives (2) Such uniform statutes should make no distinction between felonies and misdemeanors, nor between courts of record and those not of record

"(3) These identical statutes uniformly should carry the threat of imprisonment for disobedience (4) They should provide for a hearing in favor of the witness, to avoid constitutional objections and the misuse of the process (5) They also should provide adequate compensation for the witness' time lost and for payment of his traveling expenses This would discourage ill-considered use of the power

"(6) The laws of the respective states should be amended to authorize when needed the use of testimony of absent-from-the-state witnesses where a warrant is to be issued, or where a grand jury indictment is to be sought Such depositions should be taken as in civil actions, under proper safeguards and authentication, and necessarily without the privilege of cross-examination to the defendant who, under accepted principles, is not required to be informed of the pending proceedings"

Perhaps there never has been a time when the defects and imperfections in the administrations of our criminal law has compelled the attention of laymen generally as at the present time Let us hope that the states will cooperate by proper legislation, so that the prosecution may compel the attendance of material witnesses who are outside the state and refuse voluntarily to appear as witnesses for the prosecution in a criminal case

CLAIMED NEGLIGENCE IN THE TREATMENT OF A FRACTURE

In this case, a boy about nine years of age, accompanied by his father, called at the doctor's office The father gave the doctor a history that several days before, while at a summer camp the boy had injured his arm, and the camp physician had put his arm in a temporary splint with a sling and sent him home No x-rays had been taken at the time the boy first came to see the defendant

The doctor arranged to have an x-ray taken immediately This was done, and the x-ray plate revealed a simple fracture of the left arm at about the middle of the forearm. There was no non-union It was the defendant's opinion, as well as the physician's who took the x-ray, that the healing process had started and that no further setting was necessary except to place the arm in a plaster cast This was done, and the doctor instructed the father to bring the boy back in a day or two

The boy was not brought back until some two or three weeks later, when an examination disclosed that the cast was crumbling and broken The doctor asked the child and the father if the child had fallen on the cast, but they both denied it The defendant removed the cast, and found that the boy had a perfect result except for a slight bowing The doctor saw the boy on several occasions thereafter when he massaged the arm About that time, he learned that prior to the second visit of the boy to his office, several of the plaintiff's neighbors had seen the boy fall from a tree.

The father complained to the doctor about the bowing, and the doctor told him that when the boy had the cast on, he fell from a tree, and stated to the father that the only way the bowing could be corrected would be to rebreak the arm, and the doctor also recommended a bone specialist if they wanted that done The parents did not take the child to the physician suggested by the defendant, nor did they ever come back to his office.

Subsequently, both the father and the boy brought suit, claiming that the boy's arm was not properly set The plaintiffs noticed the case for trial, but about a day prior to the time when the case was about to go to trial, after fruitless attempts to force a settlement, the action was discontinued

Number 15

TRI-STATE CONFERENCE

The twelfth Tri-State Conference of the officers and editors of the Medical Societies of Pennsylvania, New Jersey, and New York was held in Pittsburgh on May 25, 1929, with Dr T G Simonton, President of the Medical Society of Pennsylvania, presiding Those present from New York were Dr H R Trick, President, and Dr J N Vander Veer, President-elect From Pennsylvania were Dr T G Simonton, President, Dr W T Sharpless, Trustee, Dr E B Heckel, Chairman of the Board of Trustees of the American Medical Association, Dr W F Donaldson, Secretary, Dr Frank C Hammond, Editor, Dr R R. Huggins, and Miss Mary Steward Blair, Business Manager of the *Pennsylvania Medical Journal* From New Jersey were Dr E R. Mulford, President, Dr J B Morrison, Secretary, and Dr H O Reik, Editor

The subject discussed was "The Ideal State Journal," and was presented by Dr Frank C Hammond, Editor of the *Pennsylvania Medical Journal* Dr Hammond discussed the ideal journal under the subjects 1, The Staff, 2, The Make-up, including paper, illustrations, and size, 3, Style of Articles, 4, Indexing, 5, Choice of Material, Bibliographies, 6, Editorials, 7, Official Transactions, 8, County Society Reports, 9, Women's Auxiliary, 10, Medical News, 11, Book Reviews, 12, Special Departments, including those adopted in the Pennsylvania Journal as follows (a) Jots and Tittles (brief editorials), (b) Medico-legal and legislative, (c) Public Health, (d) Hospital Activities, (e) Industrial Medicine, (f) Related Professions, especially dentistry and pharmacy, (g) Reporting Other Scientific Meetings, and 13, the advertising columns and pages including their relations to the reading matter

All those present discussed the subject of the State Journal at considerable length so that the session lasted from ten in the morning until three in the afternoon, and the stenographic report of the meeting covered 71 sheets Each discusser spoke from the point of view of the particular part which he is taking in his society, but the whole ensemble of the discussion would confirm the opinion expressed by Dr Donaldson, that the State Journal is first, last, and always the organ of the Medical Societies of the State and its Counties Whatever activity is carried on by the State or County Society, has its place in the Journal The peculiar field of the Journal is to record and promote the activities of the medical societies as distinguished from physicians as individuals

Dr Hammond stressed the importance of the editor being the ears as well as the voice of the various sub-organizations of the State Society, from its House of Delegates to the meetings of its committees, meaning that the editor should be invited to attend them in order that he may understand the purposes of the officers even though he might not print all that he knows

The Collection of News from County Societies was discussed by Dr Vander Veer who suggested that a field secretary could be a great source of news as he goes among the societies Dr Reik referred to the New Jersey system that each County Society should have a reporter who sends a news item after each meeting

Dr Simonton suggested an exchange of contributions among the editors of the three State Journals The doctor might have referred to the Department of "Our Neighbors" of the NEW YORK JOURNAL, in which descriptions of the activities of the other State Societies are quoted

The use of "Filler," or matter used to fill blank spaces at the bottoms of pages, was discussed and justified The speakers seemed to disagree with the attitude of the NEW YORK STATE JOURNAL that a blank space was preferable to an article which was evidently only a space filler Some of the speakers referred to news of State Society activities as filler

There was a discussion on whether reports of societies and committees should be printed verbatim according to the stenographers' notes, or abstracted and edited The attitude of the NEW YORK JOURNAL is that they shall be abstracted and edited, but the representatives of some of the other states were in favor of printing the entire stenographic reports, as they do with reports of the Tri-State Conference

The representatives from Pennsylvania and New Jersey condemned bibliographies at the end of scientific articles The NEW YORK STATE JOURNAL welcomes them, and it may be influenced in its attitude by its close association with the Library of the Academy of Medicine whose workers consider bibliographies and indexes of all kinds to be of the greatest possible value

The characteristics of a good medical editor were discussed by Dr E B Heckel, who said "Editors are not born, they are made A man may have a certain aptness for that work, but it also requires a certain amount of education and training to fit him for the work An editor must be not only honest, but also sincere It requires sincerity to run the advertising pages of any journal"

Dr Sharpless suggested that the Journals make a feature of medical histories

Dr J C Litzenberg, Minneapolis, submitted a resolution criticizing the American Red Cross for permitting its nurses to work in connection with "chiropractors and other cultists" The meeting voted to protest against this action of the Red Cross

Electric refrigerators were also discussed as follows

"A backwash from trouble in the east with electric refrigerators was seen in the motion of Dr Van Derslice of Illinois, who asked for an investigation by a committee of the danger from such gases as methyl chloride, ethyl chloride, sulphur dioxide and other gases used in the refrigerators"

The committee on hygiene of which Dr Grant C Wadell of Ogdensburg was chairman secured a vote to investigate the subject

The *Oregonian* quoted from President Thayer's address on the relation of medical to personal freedom, especially as applied to the limitation of the amount of alcohol which a doctor may prescribe

President-elect M L Harris was quoted as describing a plan for a medical center conducted by doctors as follows

The speech by President-Elect Harris included the following

"My plan, which has already been published in the Journal, consists, in brief, in each county medical society incorporating and forming a medical center with a headquarters properly equipped for the diagnosis and treatment of all varieties of ambulatory patients The organization should be in a sense a pay clinic owned and controlled by the profession Every person receiving services should pay Those who are able to pay regular fees should have their own physician, as at present Those not able to pay regular fees should be treated at the Center and should be charged a fee depending on their economic status and the character of the services rendered

"Those who are unable to pay anything are charges on the community and should be paid for by the community, at rates to be agreed on by the community and the organization The Center should be managed by a board of directors, which should arrange for the time and service that each is to devote to the work of the Center The income, which will be considerable, after paying the running expenses and upkeep will go toward paying in an equitable manner those who do the work Services eventually may be extended to patients of the same class at their homes or in hospitals, in fact, the hospitals, which should be controlled and managed by the profession, should form a part of the general organization

In the large cities more than one Center may be developed as may be necessary so as to care for those living in all sections of the city The whole scheme depends simply on the ability of the profession to organize on a business basis The importance of the subject demands the attention and thoughtful consideration of this house of delegates" No action was taken on this proposal

The scientific exhibit was described as follows

"If your nose is too long or humpbacked or out of joint, if you are expecting another mouth to feed at your house, if Patricia Ann's legs have a tendency to become estranged on the trip from knee to ankle, if you think your nervousness is caused by thyroid trouble, but someone has told you it's para-thyroid, if you haven't met vitamin B, or if you don't know how simple it is for a doctor to see through you, as well as your pocketbook, these days, you should visit the American Medical Association's exposition in the public auditorium

"You should see it for yourself, but you will be obliged to see it through these eyes of your "doc," because the board of trustees has decreed that its committee and exhibitors will have their hands full in educating members of the profession without attempting to enlighten the lay mind on the late developments in the science of trying to keep well or get well It takes a "Fellows" badge to crash the gates, and they have more guards around the exposition than walk the walls of the penitentiary at Salem

"So in the interim between now and the next time you persuade yourself to call on the learned gentleman who makes you say "Ah" when you feel more like saying "Darn," the press will have to be relied upon to give you such impressions of the supplementary adjunct to the national convention of doctorial geniuses as seeped through the maze of "ics" and "ists" and "isms" during an excursion through the labyrinth of neatly arranged exhibits"

Concerning the scientific sessions the newspaper says

"The principal interest of the medical men will center in the various scientific meetings These scientific meetings will be held galore In other words, one can't go to one place and hear it all Medicine and surgery are so highly specialized that a dozen clinics or meetings will be going on at once

"The sessions are so highly technical that they will not be of general interest, and the public will have to be content with the lectures scheduled for Lincoln high school auditorium each night, which are free" This year's meeting seems to have been unusually harmonious, interesting, and practical

PUBLIC RELATIONS COUNTY SURVEY No 8—JEFFERSON

Jefferson County has a population of 86,000 The City of Watertown, the County Seat, with 33,800 population has 53 physicians, and every year or so one is added The villages and rural sections of the county, with a population of 53,200, have in all less than 35 active resident physicians as follows Adams, 3, Adams Centre, 1, Brownville, 1, Dexter, 2, Cape Vincent, 1, Clayton, 3, Depauville, 1, Ellisburg, 1, Evans Mills, 1, Sackets Harbor, 1, Black River, 2, Chaumont, 1, Three Mile Bay, 1, Mansville, 2, Philadelphia, 2, Theresa, 2, Carthage, 9 Of these several are inactive

In the City of Watertown are two general hospitals, both with open staffs, to election to membership in which all members of the County Medical Society in good standing are eligible The personnel of the staffs of both hospitals in one capacity or another is much the same Both hospitals are rated as *Class A* by the American College of Surgeons The House of the Good Samaritan has 135 beds, Mercy Hospital 114 beds Neither hospital cares for mental nor contagious cases The city maintains an adequate contagious hospital, the gift of a public spirited citizen

The County Hospitals are two The County Contagious Hospital at Calcium is adequate

The Jefferson County Sanatorium, Watertown, N Y, has 36 beds for treatment of tuberculous cases in the county Diagnostic chest clinics are conducted weekly at the sanatorium and at the Health Center, Watertown, in cooperation with the Watertown Department of Health for cases referred by physicians for examination The Sanatorium is making r-ray studies of the lungs of the high school children of the county Field nursing is done by the tuberculosis nurse in the City of Watertown and one covering the remainder of the county The sanatorium cooperates with the County Tuberculosis and Public Health Association in all branches of tuberculosis work and in conducting a summer health camp for children A new building of 40-bed capacity for children is to be built this year

There is no provision in the county for hospitalizing the insane

The health officer of the City of Watertown serves on part time He is assisted by a sanitary inspector and two nurses one for contagious disease and one for tuberculosis The City Board of Education maintains a full time school physician, and assisting her are a high school nurse and two grade-school nurses

The city physician is on part time Through private philanthropy, Watertown, has a health center in the Memorial Health Building Here is located the office of the City Health Officer, and under his supervision a tuberculosis clinic and a genito-urinary and syphilis clinic are held weekly in this building by the city

Here the Visiting Nurse Association maintains the following weekly clinics conducted by local physicians and surgeons without remuneration Under the division of Child Welfare are three clinics prenatal, baby and preschool Besides prenatal care and instruction, provision is made for the care of indigent mothers at confinement and post partum The association provides also a weekly eye clinic and a weekly nose and throat clinic with operative and hospital care when needed From her office in this building the Superintendent of the Visiting Nurse Association administers nursing care to many indigent, and the association has recently established an hourly nursing service

The staff of the St Lawrence State Hospital conducts a mental clinic at the House of the Good Samaritan, Watertown, the third Wednesday of each month for adults and the following Friday for children

In nearly every town in the county the local department of health has held clinics for administration of toxin-antitoxin, and a large per cent of the children are immunized against diphtheria

Among health activities in city and county must be mentioned the work of the District Health Officer assisted by the state nurse, who in turn directs the work of the three Shepard Towner nurses, also, the work of the County Tuberculosis nurse, the Metropolitan Insurance nurse and of the full time health nurse maintained by the Village of Carthage

The county employs two physicians the Superintendent of the County Sanatorium and the County Physician The latter on part time has charge of the inmates of the County Home and the Jail

The Medical Society of the County of Jefferson, which previously had held meetings quarterly, took on new life and energy after its amalgamation with the Medical Society of the City of Watertown in January 1926, since when the meetings have been held the second Thursday of each month, July and August excepted The annual meeting is in November Out of a membership of 84 the average attendance is 39

Though there has been increasing interest manifest in matters of polity and public health, etc, probably the thing of most value which the society has been able to offer its members has been the excellent postgraduate lectures furnished by the State Society In the preceding four years there were given courses in obstetrics, pediatrics, gastroenterology and cardiovascular disease, and this spring a variety of topics proved no less instructive

The Public Relations Committee was instituted in October, 1927, since which time the following

Dr Heckel suggested that death notices be made a feature of the Journal

The value of obituaries of physicians regardless of the importance of the men, suggests the value of any news item of individual doctors The policy of the NEW YORK STATE JOURNAL OF MEDICINE is that a news item shall be on a subject of permanent value, one which doctors twenty-five years from now will seek out as illustrating the progress of an idea.

Dr Mulford advocated a special department given over to the Woman's Auxiliary

Dr Vander Veer suggested a loose-leaf medical journal so that a doctor could take out the articles which he wishes to read The ideal of the NEW YORK STATE JOURNAL is to make every part so interesting and valuable that every doctor will want to read the whole Journal from cover to cover This ideal might be achieved, but it would require the services of several expert editors to boil down the items and articles and put them in a form of compelling attraction

There was some discussion on preparing an outline of every article to be printed at the beginning of the article This suggestion would be ideal if authors would be logical and concise in their writing, but it is seldom practical

Book reviews were not enthusiastically praised by the representatives of Pennsylvania and New Jersey The only books which the *Pennsylvania Journal* review are those of publishers who advertise in the Journal.

The NEW YORK STATE JOURNAL policy is to conduct the book review department as a matter of information, be it with praise or with condemnation, and to have the reviewer sign or at least initial his review

Indexes were discussed briefly by Dr Hammond, who disagreed with the NEW YORK JOURNAL'S policy of indexing the articles by broad groups of subjects Dr Hammond considered that indexing is technical work requiring special skill and knowledge, and the result might require more space than the Journal could give.

Those who read the Journals of Pennsylvania, New Jersey, and New York and are well acquainted with the officers and other leaders in the State Medical Societies of the three States, will agree that each Journal reports the activities of its constituent societies, and reflects the opinions and aspirations of their officers and members

---

THE GREATER NEW YORK PERIODIC EXAMINATION COMMITTEE

By resolution introduced and favorably voted, the Comitia Minora appointed a special committee instructed and empowered to conduct a periodic health examination campaign during the month of November 1929 This committee, consisting of Doctor A J Rongy, Chairman, and Doctors Frederick W Bancroft, Eugene Lyman Fisk, Iago Galdston, S Dana Hubbard, Orrin S Wightman' and Linsly R Williams, has enlisted the cooperation of the other four county medical societies, each of which has appointed a similar special periodic health examination committee responsible for the execution of the program formulated in their respective territories

The Greater New York Periodic Health Examination Committee was subsequently formed, consisting of the above named, together with the chairmen of the four county medical committees, for Brooklyn, Dr Alec M Thompson, for Bronx, Dr Friedman, for Queens, Dr William J Lavelle and for Richmond, Dr A E Bernstein

A series of meetings has been held and a program of activities has been formulated The objectives of the campaign have been defined as follows

1 To popularize a periodic health examination among physicians
2 To popularize the periodic health examination idea among the public
3 To place special emphasis upon the desirability of having the periodic health examination administered by the family physician

In the attainment of these objectives, it is planned to enlist the aid of public utility organizations, moving picture theatres, the radio, the press, public official agencies, public school system, the charity organizations, and religious and social bodies

The execution of the plans, the details of which will be given in a subsequent report, involves the raising and expenditure of a budget of approximately $10,000 As part plan for securing these required funds, the committee contemplates the publication of a special journal

The committee sincerely solicits the active support of every physician in Greater New York

IAGO GALDSTON, M D,
Secretary

SUFFOLK COUNTY

From the News Letter of the Suffolk County Medical Society for June 1929

The regular Semi-Annual meeting of the Suffolk County Medical Society was held at Leo's Inn, Patchogue, N Y, Thursday, May 2nd, 1929, Dr E Raymond Hildreth, President, presiding Forty-nine members of the Society and eleven guests were in attendance

Dr G A Silliman submitted his report as Treasurer, covering the period from Jan 1st 1929, when he assumed the office

Public Health Committee Dr Frank Overton, Chairman, read the report of this Committee

Legislative and Public Relations Committee Dr Ross, Chairman, reported that 182 bills pertaining to the practice of medicine or health measures, had been introduced during the past session of the Legislature The usual lot of cult bills were introduced and all defeated

County Health Dept Dr Wm H Ross, President of the Board of Health, spoke of the work of the Department since its organization in January Dr Arthur Davis, County Health Officer also spoke of the work and plans for the future He mentioned the fact that it was much more satisfactory to carry on the work where Health work was inaugurated by the medical profession, and the officials were physicians and had the active cooperation of the general practitioners He contrasted other states where the majority of Health officials were laymen

Miss Glendenning of the State Commission for the Blind spoke of the need for more thorough examinations of the eyes of school children and facilities for the correction of defects She requested the Society to arrange for eye clinics and stated that in some of the counties examinations were made by optometrists It was the consensus of opinion that the children with eye defects should be examined and treated by Physicians trained in Diseases of the Eyes Dr Frank Overton stated that there were qualified eye specialists in Suffolk County

Cancer Committee Dr Ross stated that efforts had been made in the campaign for the education of the public regarding cancer, early symptoms and necessity for early treatment It was brought out in the discussion that talks before lay audiences and associations had been made by the following members Drs Ross, Baker, Hildreth and Overton Dr Kolb stated that he had received requests for and had supplied literature to a number of the physicians appointed as local representatives of the Committee at the Annual Meeting of the Society

Dr Ross stated that because of lack of time it was difficult for the physicians to devote as much time as was necessary to this subject and stated that a paid Secretary would be needed He suggested that some of the County Societies funds might be used for this purpose It was also suggested that the Tuberculosis and Public Health Association and the County Health Department would be willing to assist in this work Dr James MacIvor, of Port Jefferson, and Dr Stanley P Jones, of Mattituck, were elected to membership At 1 30 dinner was served

After dinner, Dr Luther Fish Warren, Professor of Medicine, Long Island College Hospital Medical School delivered an interesting and instructive talk, illustrated by lantern slides on "The Various Clinical Syndromes of Coronary Thrombosis"

activities of the Society in relation to Public Health may be mentioned

December 15, 1927, a committee was appointed to cooperate with the State under the Shepard Towner act in conduct of Preschool Clinics through the county

March 8, 1928, the Society endorsed the Campaign for Early Diagnosis of Tuberculosis conducted by the Tuberculosis Association

The Society pledged its support to a state-wide platform for the control and direction of medical and health matters by the Medical Profession

A resolution was adopted requesting that members report all cases of venereal disease in school children of the City of Watertown to the School Physician

May 10, 1928, the President and Secretary were constituted by the Society a committee to appoint some prominent citizen from our county to interest himself in cooperation with the Society in matters of public health as a member of an organization being formed by the State Society to assist the profession against vicious legislation and to protect the public against cults and charlatans Mr C W Valentine, of Watertown, President of the Board of Trustees of the House of the Good Samaritan, was appointed

This spring, through the cooperation of the Public Relations Committee with the school physician and school officers and the Division of Social Hygiene of the State Department of Health, lectures on Sex Hygiene were given by six of our members to the boys and by one of them to the girls of the high school The children were addressed in small groups in an informal way and questions were encouraged Following the completion of these a talk was given to the boys of the high school in the school auditorium by a social hygiene lecturer of the State Department of Health at the close of which moving pictures illustrative of venereal disease were shown Previous to this, lectures had been given by a lecturer from the Social Hygiene Division of the State Department of Health to some of the grade school girls and the mothers

October 11, 1928 a committee of three was appointed to further the administration of toxin-antitoxin

November 9, 1928, a resolution was passed favoring the proposed addition to the County Tuberculosis Sanatorium and pledging the unanimous support of the Society to the Board of Managers in their effort to secure such an appropriation

At the May meeting 1929 the Society endorsed the plan of its Public Relations Committee for the examining and conditioning of preschool children of the City of Watertown in a campaign conducted by the Parent Teacher Associations of the city The plan provided for the employment of the examining physician chosen by the parents or guardians of the children, indigents to be examined free, and for a careful check-up on those claiming to be indigent The work has been running smoothly with all concerned cooperating and already much corrective work has been done

The Jefferson County Tuberculosis and Public Health Association has the following functions, public health education and publicity, maintains children's Health Camp, takes part in diphtheria prevention campaign, assists the Sanatorium in conducting x-ray clinics in high schools, assists in enactment of necessary public health legislation, has full time trained executive secretary

The Watertown Committee on Prevention of Tuberculosis functions to interest the City of Watertown along the same line as the County Tuberculosis and Public Health Committee.

Among Social Welfare agencies of the county undertaking health work are the Luncheon Clubs The Rotary with its work among Crippled Children, Kiwanis with the Under Privileged Children and the Exchange Club with the Fresh Air Children The Benevolent Club is also active in providing food and clothing and medical care for indigent families, particularly children The shoe fund of the Elks is not an unimportant health measure The Salvation Army promotes healthful conditions among the needy The Bureau of Charities and Correction lifts children out of unhygienic surroundings and not infrequently brings to light unhealthy conditions associated particularly with venereal disease The local branch of the Child Conservation League is actively engaged in raising funds for the establishment and maintenance of a Day Nursery in the City of Watertown

The Nurses of District No 6, New York State Nurses' Association maintain a Nurses' Registry, the board of Directors consisting of 20 graduate nurses, 3 physicians and a layman The registry ably serves the whole county

In some rural districts the health officers are feeling the need for more cooperation of physicians with their local health boards But in many cases the health officer is the only physician in the locality Greater publicity for proposed health measures in the country is also needed

A much needed aid in promotion of health in our county is a County Laboratory to facilitate clinical laboratory examinations, especially for the poor, and also bacteria counts from milk, examination of water, etc

There is urgent need for some provision for the housing and proper care of acute mental cases without committing them, and that of other cases of insanity prior to commission

J D OLIN

Editor's Note—The progress of the Jefferson County Medical Society during the last four years is shown in a striking way by a comparison of the present survey with that published in this Journal of September, 1925 page 910

SCIENCE IN VERSE AND RHYME

It is not the policy of the NEW YORK STATE JOURNAL OF MEDICINE to print jokes for the purpose of raising a laugh, or verses for the sake of their unexpected twists of thought, but now an then rhyme and rhythm aid in setting forth a scientific fact.

Something over a year ago the explorer, Stefansson, began to live on a meat diet such as one would have to adopt when stranded in Arctic regions, and the end of the year's experiment found him in good health John Alden, in the Brooklyn *Eagle* of July 15th, demonstrates the possibility of recording a scientific fact in clear attractive verse when he writes

"The record's in, the task is done;
In dieting on meat alone,
The great Vilhjalmur Stefansson,
With R M Andersen, his pal,
Have scored success phenomenal,
And stood a twelve-months' test,
Four-fifths of all the meat was fat,
But proteins gave zest to that,
Digestion seemed the best.

Unsweetened coffee, strong black tea,
With water taken frequently,
Were features of the inquiry,
But each thrift-lover stares,
At present prices charged for meat,
Quite other things he has to eat,
Or sink in budget snares,
Though not devoid of interest,
All academic is the test—
Except for millionaires"

RADIUM POISONING IN INDUSTRIES

The poisonous effects of radium have been well known, and precautions have been taken to protect handlers of radium such as that used in making luminous dials for watches Yet fatal poisonings have occurred; and now the New York *Sun* of July 10th, states

"Scientists of the United States Public Health Service now are engaged in the task of making painstaking examinations of between 100 and 200 factory workers who have been exposed to radium rays in an effort to save them from the ravages of a dreaded new industrial disease"

"Dr L. R. Thompson, who has charge of the radium survey, explained today that an effort is being made to examine every worker in this part of the country who has been exposed to radium rays There are now forty-two known radium poisoning cases in the country, and the disease has taken a toll of twenty-one deaths, he said

"Workers examined have not necessarily been injured by the radium rays," Dr Thompson added, "as many persons have worked with radium over a period of years without any ill effects Harm has come mostly in cases where girls in clock factories pointed radium-tinted brushes with their lips The practice has been discontinued."

BROTHERHOOD IN NEW YORK CITY

Incivility in New York is the title of an editorial in the New York *Times* of July 10th The article was founded on an item which appeared in the *Vancouver Star* complaining that

"Clerks in shops, theatre ticket sellers, street car conductors and subway guards, as well as pedestrians in the streets, all gave him 'an impression of hardness and cruelty that is not obtained in any other city I have been in'"

The *Times* adds the comment

"We are fortunate in having few visitors with such unfriendly memories of us"

It happened that the New York *Herald-Tribune* of July 10th, commented editorially on the humanity of New Yorkers as shown by the immense Sunday crowds which flock to Coney Island where selfishness and discourtesy should be most in evidence if those charactertistics were dominant among New Yorkers The editorial says:

"It is very wonderful, indeed After reading newspapers for six days, with their record of the follies, the sins and stupidities of the human race, it would seem incredible that any one could still retain so large a liking for the human race as deliberately to place himself in the center of a crowd on Coney Island But people do, the numbers who flock upon the sands in bathing suits are limited, not by the area of sand available, but by the capacity of the bathhouses only It is a final proof that there must be something good about humanity after all. Somebody still loves it"

What seems to be incivility in New York is principally speed—without which modern life in office buildings and subways could not exist. When a real need develops, an individual will be treated more kindly in New York than in any other city

THE DAILY PRESS

CHILD HEALTH CONFERENCE

The New York daily papers of July 3 carry the announcement that President Hoover will call a national conference on child health to meet early next year The *New York Times* says that a special object of the conference is to devise plans for increasing the sanitary and recreational facilities in the schools The conference will be under the direction of the Secretary of the Interior, Dr Ray Lyman Wilbur, who was president of the American Medical Association in 1923 President Hoover is quoted as follows

"In order that these determinations may be effectively made and intelligent presentation given at the conference, a series of committees will be appointed from the leaders in different national organizations and will be assisted by experts

"The subjects to be covered embrace problems of dependent children, regular medical examination, school or public clinics for children, hospitalization, adequate milk supplies, community nurses, maternity instruction and nurses, teaching of health in the schools, facilities for playgrounds and recreation, voluntary organization of children, child labor and scores of allied subjects

"To cover the expenses of the preliminary committees and the conference and follow-up work which will be required to carry out the conclusions of the conference, a sum of $500,000 has been placed at my disposal from private sources

"This will be the first national conference held in review of this subject since the conference called by President Roosevelt in 1909 That conference resulted in a great impulse to social and protective activities in behalf of children"

CODE OF ETHICS FOR TEACHERS

In the department of Daily Press for June 15, reference was made to a code of ethics for ministers of the Gospel The *New York Times* of July 3 contains an editorial on a code of ethics for school teachers, which says

"The code of ethics adopted by the National Education Association seems almost self-evident It is not surprising that the vote of approval should have been unanimous, for the code merely puts into orderly expression what has been already adopted in actual practice

"It is, for the most part, a code of warning to those who are constantly asking the schools to do something to further their selfish ends or promote their causes, however good. It is virtually a notice posted at the schoolhouse doors informing the public that propagandists, whether political, religious, social or personal, are not admitted The school is so convenient an agency for reaching the whole population of a community, for getting into every home, for attacking some evil, for initiating some reform, that there is a great temptation to trespass upon its strictly educational work and to divert the interest of the teacher from professional duty

"It goes without saying that teachers should not tutor pupils in classes for pay nor accept royalties or commissions for books or supplies which they have had a part in selecting This is elementary ethics But it cannot be said too emphatically or too often that the school and the teacher must not be used as convenient means for the spreading of propaganda, the promotion of outside enterprises, or the solicitation of funds This 'code of ethics' should be taught the public by the teachers They deserve to be protected from such intrusions upon their higher tasks"

There is an ambiguity about the ban on royalties for school books It would seem that the practical teacher of arithmetic, or history, or reading, would be the very best person to create a text-book on the subject Financial returns and high positions follow hours of sociability on the golf course quite as certainly as months of labor in the cloister of a temple of learning Physicians demand that those who practice any branch of the healing art should publish the results of their experience, and they are glad to see medical authors receive a financial profit from their literary work

REPORT OF THE INTERNATIONAL CONFERENCE ON CANCER, LONDON, 1928 Held Under the Auspices of the British Empire Cancer Campaign. Octavo of 588 pages. New York, William Wood and Company, 1928 Cloth, $12.00

It is not very often that a medical conference is formally opened by a King The fact that King George made the address of welcome to the Delegates to the International Conference on Cancer signifies its importance to the world in general and to the medical profession in particular King George's reply to Sir Bland-Sutton's address, outlining the purposes and aims of the Conference, reveals the sincere and human side of a kind and sympathetic gentleman. No group of workers to say the least the cancer Specialists, could possibly mistake the sincerity of the King's remarks Neither could they mistake the gravity of the problem for which they were called in conference. It surely must have been a stimulating moment and we believe, having as it did for its objective the segregation of all the known facts regarding the cause and cure of cancer, was one of the most important conferences ever indulged in by the medical profession. In many ways Cancer remains an unsolved problem and is of vital interest to every civilized country on earth. What subject could be of more importance to the physician and surgeon?

This report constitutes a volume of 588 octavo pages It contains the welcoming address of Sir John Bland-Sutton, the King of England, the Duke of York, who is President of the British Empire Cancer Campaign, the personnel of the Grand Council of the British Empire Cancer Campaign, officers of the Conference, names all overseas Delegates, with country from which they came, names of Delegates from the British Dominions and Home Delegates and members Then follows a table of Contents under the following headings

1 Etiology of Cancer (General Discussion)
2. The Relative Value of Surgery and Radiation in the Treatment of Cancer
   (a) Treatment of Cancers of the Cervix, Breast, and Buccal Cavity
   (b) Statistical Evolution of Results
3 Methods of Treatment by Chemotherapy with Special Reference to Head.
4 Section of Pathology—Occupational Cancer
5 Section of Surgery
   (a) The Early Recognition of and Treatment of Cancer of the Stomach.
   (b) Sarcoma of the Bone.
6 Section of Medicine.
   (a) Consideration of Cachexia.
   (b) Cancer of the Lung
7 Section on Diagnosis—Diagnostic Methods in Relation to Cancer
8. Section on Radiology
   (a) Effects of Radium and X-rays on the Blood, Vascular and Lymphatic Systems with Special Reference to Malignant Growths
8. (b) Biological Effects of Radium and X-rays with Special Reference to the Factors of Wave Lengths Intensity of Radiation and Duration of Exposure.
9 Section of Statistics and Public Health.
   (a) The Geographical and Racial Prevalence of Cancer
   (b) Public Action in Regard to Cancer

Certainly this volume contains the greatest array of cancer facts extent today In the space allotted, no Reviewer could possibly discuss seriatim the many problems brought before this Conference. Your Reviewer, however, has read the volume (most of it very carefully), and he can unconditionally recommend it to all students of the cancer problem. To be sure, there are few if any new facts (for there are really none known), but this book contains all the worthwhile data pertaining to cancer

H. B. M.

PHYSIOLOGY AND BIOCHEMISTRY OF BACTERIA. Volume I Growth Phases, Composition, and Biophysical Chemistry of Bacteria and their Environment, and energetics By R. E. BUCHANAN, Ph.D, and ELLIS I. FULMER, Ph.D Octavo of 516 pages Baltimore, The Williams and Wilkins Company, 1928 Cloth, $7.50

This is the first volume of a contemplated series dealing with the physiology and chemistry of bacteria, yeasts, and molds The outstanding characteristic of this work is *completeness* It contains practically everything known to science pertaining to the subjects treated. It is, therefore, an extremely useful reference work to which the investigator can turn for information on any subject included in its scope, and be certain of finding a complete and understandable exposition of the known facts, with details as to methods and interpretation of results.

The subjects considered in this volume are growth phases and growth rates in cultures of microorganisms, the chemical composition of bacteria, yeasts, and molds, colloid and physical chemistry as applied to bacteriology, growth and movement of bacteria and their utilization of energy In the discussion of growth phases and growth rates of bacteria, numerous graphs are given, reproduced from the original literature, and the underlying mathematics discussed at length. Under the topic of chemical composition of microorganisms, methods of analysis are described, as well as the results of such analyses Over half of the book is devoted to a very complete exposition of colloid and physical chemistry as applied to modern bacteriology Such difficult subjects as the Donnan membrane equilibrium, hydrogen ion concentration, and oxidation-reduction potentials are discussed more clearly and fully than in any recent text. In the last section of this volume, chemical thermodynamics (a subject on which most bacteriologists are densely ignorant) is taken up, as well as the problems of energy production and transformation by bacteria.

A. H. EGGERTH

POCKET ATLAS OF ANATOMY By VICTOR PAUCHET and S. DUPRET 12mo of 306 pages, illustrated. New York, William Wood and Company, 1928. Cloth, $4.00

This little anatomical atlas is a volume of the quiz compend type and represents the combined efforts of a medical author and an anatomical draughtsman. There is no text—merely a series of illustrations, with appropriate markings, of all the skeletal, visceral and nervous systems of the body The illustrations are well-executed, appropriately colored in most instances and properly marked. As a handy reference book or as an aid for the rapid review of anatomical data, the volume should prove very useful.

FRANK E. MALLON

ERYTHEMA NODOSUM. By J. ODERY SYMES M.D 12mo of 72 pages, illustrated. New York, William Wood and Company, 1928. Cloth, $2.00

In this monograph the author has delved quite fully into the history of about two hundred fifty cases of this disease, and has examined these patients carefully The question of etiology is discussed most fairly, and the pathological histology of a few of these cases has been described very thoroughly

The clinical course of the disease is outlined, with consideration of cases showing fairly definite contagion, also other cases having numerous recurrences The relationship of Erythema Nodosum to Tuberculosis is considered, and it is rather surprising to read the histories of patients developing acute tuberculosis within six months, and occasionally up to two years after recovery from Erythema Nodosum.

The author points out the necessity of considering the patient from more serious angles than simply that of having a skin disease from which he fully recovers within a short period of time.

E. ALMORE GAUVAIN

BOOK REVIEWS

LOCAL ANESTHESIA A Short course for Students and Surgeons By GÉZA DE TAKATS, M D Octavo of 221 pages, illustrated Philadelphia and London, W B Saunders Company, 1928 Cloth, $4 00

This is a well-written treatise on local anesthesia

The author first takes up the history of local anesthesia and then progresses step by step from the indications and counter-indications through the various methods employed when performing certain types of operations

It is a book to be recommended to the surgeon (both general and special) for a careful perusal when contemplating using a local anesthetic for major operations

The methods of anesthetizing the various abdominal regions, the subperitoneal organs, extremities, etc., are very well described

The book in general shows the result of the careful study of the author W A COAKLEY

THE NEW POCKET MEDICAL FORMULARY By WILLIAM EDWARD FITCH, M D Fifth Edition. 16mo of 501 pages Philadelphia, F A Davis Company, 1928 Flexible leather, $3 00

This excellent little formulary, now in its fifth revised edition, offers many changes that add to its usefulness Many new formulae have been added. The section on Dietotherapy has been improved by the addition of new diet lists

A book of this kind gives the student a practical idea of the art of prescribing and at the same time offers the busy doctor a variety of remedies that may be employed in the treatment of a great many of the more important diseased conditions The diseases are arranged alphabetically F S

HUGHES' PRACTICE OF MEDICINE. Including a Section on Mental Diseases and One on Diseases of the Skin By R. J E. SCOTT, M A., B C L, M D Fourteenth Edition 12mo of 839 pages, with 63 illustrations Philadelphia, P Blakiston's Son and Company, 1928 Flexible leather, $4 00

With the great addition to medical literature and knowledge, it becomes a more difficult task to condense the field of medicine in a single small volume The Fourteenth Edition of this book is ample proof that it meets a demand which one is inclined to believe is principally from the student body For the limited space allowed, the articles must necessarily be very brief and condensed, but they are well written. Several new articles and additional material appear on avitaminoses, actinomycosis, diabetes, asthma, etc. H W

RECENT ADVANCES IN PHYSIOLOGY By C LOVATT EVANS, D Sc., M R C S Third Edition 12mo of 403 pages, with 86 illustrations Philadelphia, P Blakiston's Son & Company, 1928 Cloth, $3 50

This new edition of the volume in the "Recent Advances Series" has been amplified by new chapters on excitability and the nervous impulse The remaining chapters have been revised, those on the mechanism of tissue oxidation and the chemistry of muscle contraction being especially interesting and complete. The chapters on the blood gases and reaction of the blood constitute a really important compendium of the facts resulting from recent work in this field. This volume serves to bring any larger text, not so easily revised, up to date. References to original articles are appended to each chapter A GOERNER.

LIGHTING IN RELATION TO PUBLIC HEALTH By JANET HOWELL CLARK, Ph D Octavo of 185 pages, illustrated Baltimore, Williams & Wilkins Company, 1924 Cloth, $4 00

This book is quite technical However the explanations are well written and clear up many points which have been misunderstood in the past regarding proper lighting effects It describes particularly the various kinds of illumination and how they may be used to the best advantage. The chapter on "diseases attributed to light and heat" is good but a more lengthy discussion of these diseases would make it a greater asset.

This book is of invaluable aid to the sanitarian who must supervise lighting conditions in schools, industries, and other public buildings J J W

THE DIABETIC LIFE ITS CONTROL BY DIET AND INSULIN A concise Practical Manual for Practitioners and Patients By R D LAWRENCE, M.A., M D Fourth Edition Octavo of 188 pages, illustrated. Philadelphia, P Blakiston's Son & Company, 1928 Cloth, $2.50

This is a most useful little book. It is simple enough to be of help to the patient and yet there are a good many things which a physician can learn from it. The discussion of the ketogenic-antiketogenic ratio is most illuminating and extremely simple

The author's line ration scheme of dieting, as well as the five-gram scheme, are as clever as they are helpful. While not quite as simple as the author considers them to be, they are as simple as a diet scheme can be made if accuracy and variety are both to be considered

The author has an easy flowing style which makes the reading of the book not a task but a pleasure.
BENJAMIN DAVIDSON

THE PRINCIPLES OF SANITATION A Practical Hand book for Public Health Workers By C H KIBBEY Octavo of 354 pages, with 34 illustrations Philadelphia, F A Davis Company, 1927 Cloth, $3 50

This is a well-written work giving a bird's-eye view of sanitation We like the order which is followed in describing the divisions of each topic. It is written for lay people and from this standpoint is excellent in that it uses practically no technical terms One can get a fine comprehensive view and remember the outstanding factors in controlling disease

It should be admirable for the average high school student. J J W

A TEXT-BOOK OF PATHOLOGY By W G MACCALLUM Fourth Edition Octavo of 1177 pages, illustrated Philadelphia and London, W B Saunders Company, 1928. Cloth, $10 00

A new edition of this splendid text-book is always welcome. Physically, this volume is somewhat more compact than its predecessors The author has brought it as completely up to date as possible by a complete revision of every chapter It is not possible to indicate the many changes in the text but on reading certain sections one notes the inclusion of recent discoveries and viewpoints in pathology The reviewer particularly liked the thorough discussion of cardio-vascular and renal pathology The discussions of chemistry, immunity, etc., appearing in previous editions have been shortened or omitted The descriptions of gross and microscopic pathology are unusually good The illustrations have always been a valuable feature of this work. This book continues to hold its place as one of the best of its kind E. B SMITH

Be sure of it, give me the ocular proof"
—Shakespeare

That Difficult Feeding Case!

THE results obtainable with Dryco, especially in cases where other forms of milk are inefficacious, will be more convincing than any verbal or written arguments expounding its merit. Year after year physicians all over the world have proved that Dryco is the ideal milk for infants deprived of breast feeding.

Due to its ease of digestibility and completeness of assimilation, the routine use of Dryco assured freedom from nutritional disturbances Non-pathogenic, it also avoids the danger of milk-borne infections Simple to prepare—keeps fresh without ice—obtainable at all druggists

Send for suggested feeding tables, Dryco samples and clinical data!

DRYCO

For convenience, pin this to your letterhead or Rx blank and mail

THE DRY MILK CO. 15 PAR ROW, NEW YORK, N Y.

OUR NEIGHBORS

PHYSICIANS IN POPULAR MEDICAL INSTRUCTION

One of the principal addresses before the Annual Meeting of the Massachusetts Medical Society was that given by Dr W H Robey, of the Harvard Medical School, on the work of the doctor in giving medical instruction to the people, which is the leading article in the June 20 issue of the *New England Journal of Medicine* The author covers the subject in a highly interesting way as is shown by the following quotations

"The public is being informed upon such subjects as art, literature, science, economics, investments, etiquette, bridge, ad infinitum Journals and public lectures give accurate information by experts on these topics and the same inquiring public is looking for similar help in medical matters Why shouldn't the public want to learn about medicine and disease? People are better educated than ever before, their minds are more receptive and perceptive Yet when you discuss medicine with your most intelligent patients, you will find a mass of superstitious survivals and distorted theories They are utterly unable to sift the wheat from the chaff, their questions indicate but small understanding of the differences between legitimate medicine and quackery

"The physician of today is still bound down by tradition Some of our colleagues look upon those who seek to teach the public as advertisers There is still a tacit acceptance in general that any form of publicity emanating from or referring to a physician, even for the public weal, is a breach of professional ethics, in that attention is called to that particular physician

"Could any one doubt the sincerity of that master of diabetes, Elliott P Joslin, whose lectures and radio talks have done so much to arrest the attention of persons temporizing with the early symptoms of diabetes, and whose manual for the diabetic has halted the victim on the brink of catastrophy Pardee and Hart have each written books for the layman to warn him of the early signs of cardiac failure, and Lord has done a similar service in pneumonia There are many others, and new authors are constantly appearing

"Every city and town has its women's and men's clubs and other groups who are showing an increasing desire to put medical papers on their programs The modest practitioner who believes that it requires a rare endowment or a long apprenticeship in writing or speaking to acquire the accomplishment of public persuasion may be consoled as I have been by the words of Peter Latham, one of the great clinicians of a century ago 'Knowledge may be an incumbrance as well as a help Many men know more than they are able to wield There is a point in the acquisition of human knowledge beyond which, if more be acquired, the whole mass becomes useless to its possessor I am acquainted with men who never have done and never can do anything because they know too much, and I am acquainted with men possessing comparatively small knowledge, so dextrous in its use that they have ridden over the heads of others, far, very far their superiors in acquirements'

"The Sunday afternoon Public Lecture Course of Harvard has been given for many years on a great variety of carefully selected subjects The speakers, who are usually drawn from the Medical School Staff, are specialists in a particular field, and the programs have from time to time been enriched by an imported expert or such a leader in public thought as our revered Bishop Lawrence, whose influence carries into the realm of things physical and by whose message multitudes are wisely directed

"The committee is not aware of the substance of the lecture before it is given, but a member is always present to pass judgment upon its value, the speaker's delivery, and its effect upon the audience Similar or related subjects may be given the following year by different speakers, especially if the topic is one which the committee feels should be kept in the public mind The public lectures are well advertised and what is more they have now become an institution They are given at a definite time each year and the public is watching for them Other medical schools, Boston University and Johns Hopkins, offer similar courses, those of the latter institution being made possible by the DeLamar Fund, comprise lectures on 'personal and public hygiene with the hope that this is the way to serve as a centre for the distribution of useful knowledge in all matters pertaining to sanitation and preventive medicine'

"The essentials of the lectures are given in the daily press and create more or less discussion among various groups If a lec-

That Difficult Feeding Case!

THE results obtainable with Dryco, especially in cases where other forms of milk are inefficacious, will be more convincing than any verbal or written arguments expounding its merit. Year after year physicians all over the world have proved that Dryco is the ideal milk for infants deprived of breast feeding.

Due to its ease of digestibility and completeness of assimilation, the routine use of Dryco assured freedom from nutritional disturbances Non-pathogenic, it also avoids the danger of milk-borne infections Simple to prepare—keeps fresh without ice—obtainable at all druggists

Send for suggested feeding tables, Dryco samples and clinical data!

turer makes a facetious remark, the reporters are sure to seize upon that and use it as a headline There may be an advantage in this provided the essence of the theme has been included, for it may serve to focus attention upon material which otherwise might be passed by In the series of medical lectures given before one of the Rotary Clubs of New England this winter, the one on cancer stimulated two women present to consult a surgeon immediately about tumors of the breast which they had been neglecting, and both proved to be early malignant disease.

"The men who care for all the sick of a community should certainly be among those to instruct the public, though often the local committee prefers to invite lecturers from a medical centre Such was the plan of the Kiwanis Club of Concord, New Hampshire, this winter However, almost every community now has an excellent hospital where a very high type of work is done, and lecturers should be drawn from its staff members or from those in the county medical society who are interested in presenting cases at its meetings. Surely some will be found in such a group who have an interest and facility in giving public instruction in the incipient signs of disease

"There is no more opportune moment for establishing the right point of view in matters medical and sanitary than during the hours of hospital life, and that without any undue strain on the part of the hard-worked force upon whose care the sick depend There are nurses (and may their tribe increase), which without seeming effort transform the mental attitude of the patient so that he leaves the hospital a messenger of better living to his community, a co-worker with us, albeit almost unconscious of his mission My plea is for greater recognition of the hospital on its educational side, for a development of its innumerable and advantageous opportunities to become one of the most far-reaching forces in our corporate civic life for the propagation of fundamentally sound health principles

"The sanatoria for the treatment of tuberculosis have done a stupendous work in teaching others than their patients through the information carried back into thousands of homes With a reduction of 60 per cent in the death rate from this disease during the past thirty years, and the assured prospect of a further and unreckonable decrease, we have the most spectacular demonstration in medical history of what a wisely organized, carefully followed up public policy can accomplish

"Frequently we are asked about the value of this or that form of cure or diagnostic pro-

cedure and we should be prepared to give a convincing explanation A contemptuous answer may prove a boomerang for the questioner is sure to go away with the belief that we are either biased or jealous and will turn to quackery even more readily than if we had praised it

'At the first hearing of the bill to license chiropractors, under a separate board of registration, the hall was crowded to suffocation, and when the advocate called upon all those present to rise who had been helped or cured by chiropractors after regular physicians had failed, the only persons who remained seated were the legislators and the six or eight doctors congregated in the center of the room. As the proponents surrounded us and glowered down, I could think only of the snow-covered sheep huddled together in Schenk's famous painting 'Winter' What must legislators and others think of such a feeble display of opposition to a bill of vital concern to our profession, and, as we believe, of far reaching importance to the laity? When requested to attend the hearing, one young surgeon said that he was too busy making a living, and a physician retorted that if the people wish to be fools let them so continue Why was there not present a phalanx of our number whose presence would have been heralded in the press and whose obvious determination to uphold the highest professional standards would have carried a weight of conviction to unnumbered readers of the proceedings, now unfortunately uncertain as to whether it is only a small coterie who are interested or what they call prejudiced? This indifference to community duty costs us dearer than we sometimes realize But the people are not fools, they are mere children in medical matters, accepting the benefits of public health measures as infants do their food and raiment, and failing to realize that victories for the common welfare have been slower and more difficult in the winning than those on the field of honor"

The report of the Legislative Committee of the Illinois State Medical Society given at the annual meeting on May 21, contained the following description of medical legislation during the last session of the Legislature as quoted from the *Illinois Medical Journal*, July issue

"The naparaths, backed by a very able attorney and a large lobby of their proponents, met a most stinging defeat in the Judiciary Committee of the House, by a vote of 20 to 0 More than half the members of the Committee present were from Cook County, which proves conclusively that the members of the Chicago

(*Continued on page 972—adv xvi*)

PUTTING HEALTHY WEIGHT ON *backward* BABIES

You find, in your practice, that the purest of milk does not always agree with all babies. The milk is frequently curdled by the natural acids and enzyme rennin in the stomach resulting in colic, regurgitation or the passing of undigested curds, preventing the body from receiving the full nourishment of milk.

It has been proved by research (and the fact is widely recognized by the medical profession) that the addition of 1% of Knox Sparkling Gelatine dissolved and added to the milk will largely prevent curdling in the stomach and thus greatly increase the nourishment derived from the milk.

There is nothing in pure gelatine that will in any way be injurious to any baby either sick or well. But precaution should be taken to use only the purest of gelatine. Knox Sparkling Gelatine has been the accepted standard for nearly forty years. It has the same neutrality as milk—is an excellent protein, unflavored, unsweetened, unbleached. Specify Knox, the *real* gelatine, when you prescribe gelatine.

The following is the formula prescribed by authorities in infant feeding: Soak, for about ten minutes, one level tablespoonful of Knox Sparkling Gelatine in one-half cup of milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the quart of cold milk or regular formula

The booklets listed below will help you in your practice. If you will return the coupon we will gladly send you complete data.

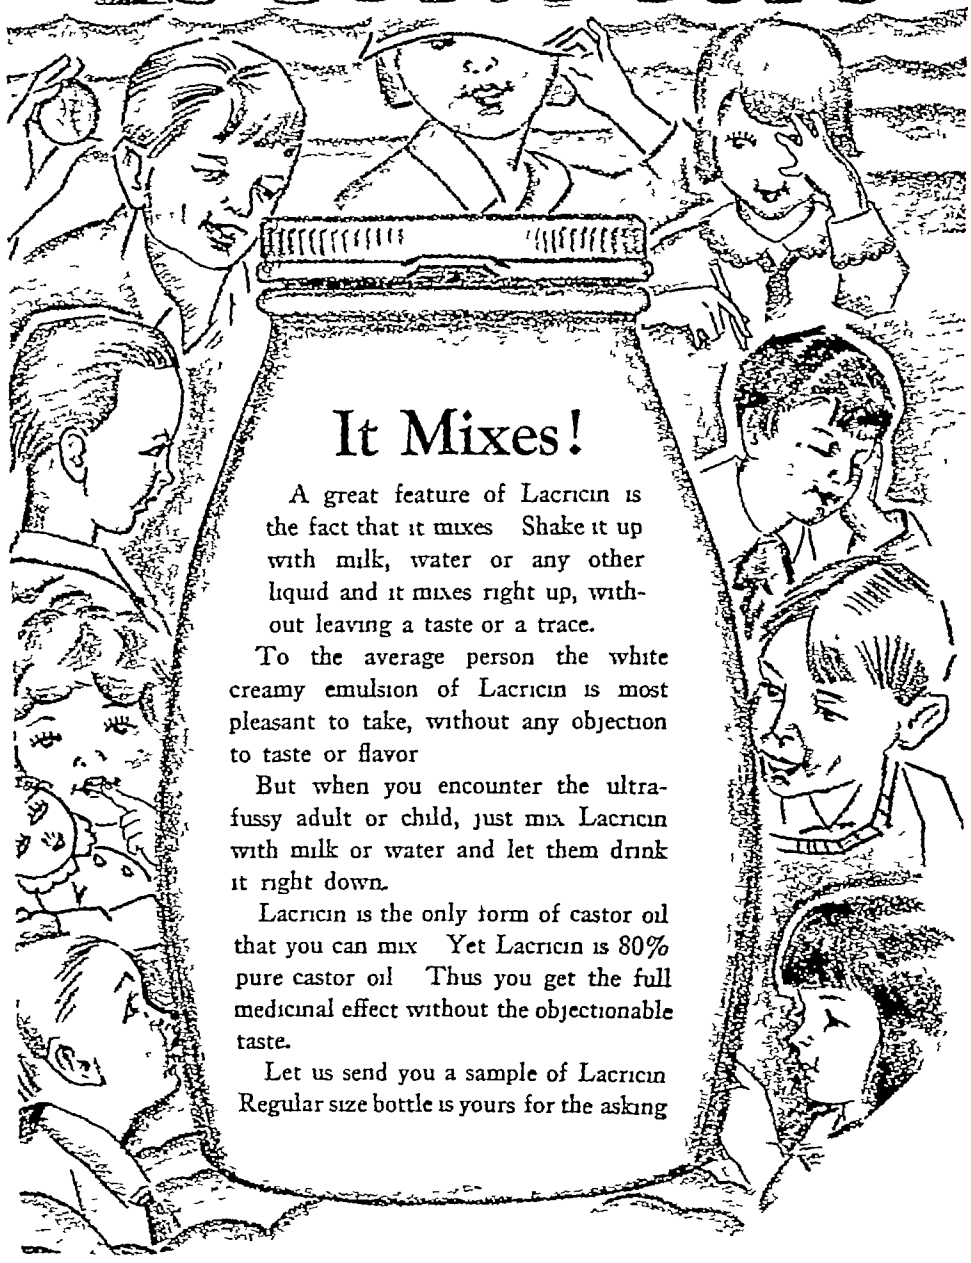
(*Continued from page 970—adv xi*)

Medical Society had done their work most efficiently The Chiropractors, in another committee composed mostly of down-state members, had their bill, also presented by an outstanding attorney, defeated by a vote of 10 to 1 There are very few bills pending that are engaging our attention at the present time Your committee believes that the Sanatology Bill will have been defeated before this report is printed A pernicious Optometry Bill is slated for an early discard

"The anti-vivisectionists have concluded that their measure will be defeated They probably are the best organized of all the groups which we had to antagonize this year The anti-vivisectionists are amply supplied with funds to carry on a most persistent campaign two years hence. This year they engaged Mr George Arliss, the prominent English actor, who recently held a meeting reception in Springfield which was attended by over 700 The hearing in the City Council Chambers of Chicago was attended by about 800 and the anti-vivisectionists are making a most desperate effort to curtail animal experimentation in the State of Illinois

"The opposition has been maintained by not only the Illinois State Medical Society but the medical colleges and other scientific groups in the State of Illinois



Several very pernicious narcotic regulations were advocated and subsequently withdrawn as the result of our protest. Another innocent looking, yet a most unfortunate bill if passed, designed to curtail chicken thieving in the southern part of the state, would place an unnecessary and unwarranted burden on the physician, in that it would hold a physician criminally responsible if he failed to report the treatment of a patient who had suffered with a gunshot wound, but it did not include everyone else having knowledge of the shooting

"A larger group of less important bills have been corrected rendering them innocent in so far as the medical men are concerned, for instance, the barber bill was rewritten, and all of the medical provisions were deleted Corrective suggestions in several other bills were accepted by the proponents It is a well known fact that bills introduced, having no opposition, stand a very good chance to become laws, which calls for careful and constant watching on our part

"As each councilor has a certain number of counties or districts under his jurisdiction it is a comparatively easy matter for him to select a legislative committee of local physicians in his district

LACRICIN

It Mixes!

A great feature of Lacricin is the fact that it mixes Shake it up with milk, water or any other liquid and it mixes right up, without leaving a taste or a trace.

To the average person the white creamy emulsion of Lacricin is most pleasant to take, without any objection to taste or flavor

But when you encounter the ultra-fussy adult or child, just mix Lacricin with milk or water and let them drink it right down.

Lacricin is the only form of castor oil that you can mix Yet Lacricin is 80% pure castor oil Thus you get the full medicinal effect without the objectionable taste.

Let us send you a sample of Lacricin Regular size bottle is yours for the asking

"The method we follow in any given councilor district is as follows Immediately after the election of a member of the legislature the councilor selects a committee of physicians who are willing workers and who, if possible, reside in the same city with the elected member, one of whom is always his family physician Frequently this group is augmented as the situation demands in any particular district

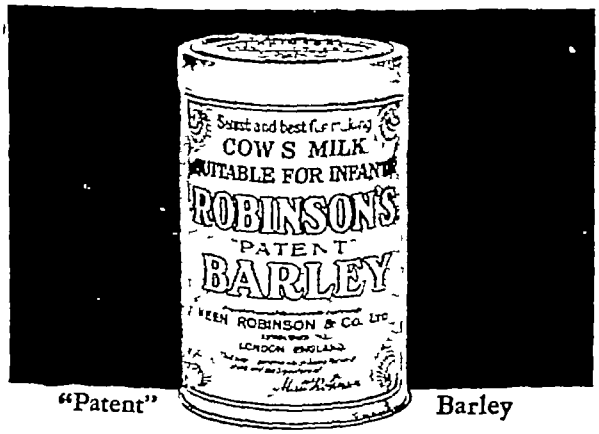
"Through the aid of the councilor a questionnaire is completed by several members of the committee relative to the particular legislator in that district This questionnaire asks for the name, address, senatorial district, occupation, politics, name of political adviser, name of family physician, attitude toward medical profession, previous legislative record, etc.

"These reports are sent to the chairman of the state legislative committee who carefully checks and correlates this information, conflicting reports are reconciled and any missing information sought Occasionally, but not often, do we have to change the personnel of the local committee, if there is laxness in cooperating, and resort to more willing workers

"We have no large medical lobbies of physicians and in this matter save an immense amount of time and expense to the profession The work can be and is done more effectively in the home districts

"Many legislators honestly believe there is a professional jealousy held by the medical men against the cults, and this propaganda is instilled into them by the cultists in a most efficient manner, and anything a physician says to this type of legislator derogatory to the drugless healer tends to strengthen this belief and many votes are cast against us through this error This thought brings up an interesting angle of our work in schooling the physician and that is 'What not to do' To illustrate In the recent Illinois Assembly a prominent physician was asked to write to the three legislators in his district opposing a certain bill creating a drugless healer's board His letter commenced as follows

"When the tornado in 1925 devastated southern Illinois there was an appeal for physicians but no invitation was extended to the pseudo-scientific charlatan the second story grafter, or the bungling ignoramus known as the chiropractor



"This is wrong, all wrong, and enhances the belief that our legislative opposition to such cult measures is based on jealous fear

"Many osteopaths, chiropractors, naprapaths, etc, are law-abiding citizens property

Robinson's
"Patent" Barley *and* "Patent" Groats

Recommended by the medical profession for over a century

"Patent" Barley

Modifier of the curd of cow's milk thus increasing digestibility of protein and fat

Non-fermentable carbohydrate addition to infant milk mixtures

1—To assist gradual development of the infant's starch digesting functions

2—To replace more easily fermentable sugars

Thickening agent for preparation of thick feedings in vomiting cases

Bland soothing fluid for administration in the early stages of infantile fermentative diarrhoea

"Patent" Groats

Finely ground, standard preparation of Oats, with a definitely laxative action

Highly nutritious cereal for weaned infants

Nourishing addition to cow's milk in the diet of the expectant and nursing mother Suitably modifies the milk and imparts to it a pleasing flavor

Of especial benefit to invalids and convalescents where cow's milk so frequently forms the major part of the diet

owners, and church members and such unkind inuendos are unnecessary, and devoid of proof If we cannot show the fallacy of their claim for special privilege legislation without delving into personalities we are necessarily making our task most difficult

"We are very glad to report that no legislation inimical to the best interests of the physicians and the public health, has been passed by the Illinois General Assembly in over 15 years, which rather demonstrates that our plan, at least, is a workable one and productive of good results

"In accordance with the usual custom, a member of your legislative committee calls on each newly elected Governor to acquaint him with the aims and ideals of the ethical medical profession, and in return, to get his opinion regarding legislation which may effect the public health Governor Emmerson has indeed been kind to your committee, and allowed them a number of conferences, and it is gratifying to know that he is for every good law to protect the people's health, and in his public life he has always respected the wishes of the ethical medical profession The Illinois State Medical Society is to be congratulated upon having a Governor who is very anxious to make Illinois one of the outstanding states in reference to the Department of Public Health He appointed as the director of that important department, Dr Andy Hall, a councilor of our society, who had the endorsement of a large group of our members With such men as Governor Emmerson and Dr Hall, the people of the state have little to fear but that the best interests of the public will be served"

PROBLEMS OF THE OREGON MEDICAL SOCIETY

The July issue of *Northwest Medicine* contains the address of Dr L B Bouvy, President of the Oregon State Medical Society, on May 16, on the subject, "Problems of Our Medical Society" Dr Bouvy said, among other things

"I wish to stress the necessity of an early anti diphtheric campaign in Oregon In 1928 the State Board of Health received reports of 543 cases of diphtheria with 35 deaths You are fully aware that by proper education and cooperation with the public all of this could have been avoided We must strongly advocate the Schick test, toxin-antitoxin in all positive cases, and another Schick test after a few months to determine whether an active immunity has been developed By his means we can hope to see diphtheria completely disappear in Oregon and all civilized localities

(Continued on page 977—adv xxi)

(*Continued from page 976—adv xv*)

"Our duty to public health education with regard to periodic health examinations must continually be emphasized The laity must realize the significance of a scientific medical education and the service which the well trained medical man is prepared to render Conversely, our limitations should be understood, so that the cultists who frequently promise so much in chronic, hopeless cases may be more thoroughly exposed

'Our best weapon for the charlatan is our own intellectual advancement which must be nourished by attendance at medical meetings, scientific gatherings, post graduate study and a firm desire to do the very best for our patients 'Chance favors only the mind which is prepared.' The more one sees of medical careers, successful and otherwise, the more one must be impressed with the importance of sound preparation A thorough education prepares one for the self-education that must follow It not only enables one to be more useful, and, other things being equal, more successful materially, but it makes one's life much easier, and thus puts one in the state to enjoy life

"Another weapon which we must employ is legislation,—not legislation for special privileges for the profession, but initiated and guided by the medical minds for protection of the public safety and advancement of medical science

"Do you know that a bill was passed providing a penalty not to exceed $1,000 fine, and one to five years imprisonment or both penalties, for any practitioner of the healing art, whether licensed or not, who fraudulently makes any false statement regarding the physical condition of any person, or who treats a person for an affliction which does not exist?

'The Basic Science Act died in the Senate Committee However, the Council of our Society decided in March to proceed with the preparation of initiative petitions to place this Act on the ballot for the general election in November, 1931

"Another bill submitted to the Senate at the last session was by the osteopaths It proposed to allow them to specialize in eye, ear, nose and throat practice Immediately the optometrists were highly offended to think of this additional competition and the Senate was besieged with telegrams and phone calls As a result the entire line, 'eye, ear, nose and throat,' was stricken from the bill and it was allowed to pass We thank you optometrists"

Summer Problem No. 3—DIARRHEA

AGAROL is the original mineral oil—agar agar emulsion with phenolphthalein and has these special advantages.
Perfectly homogenized and stable; pleasant taste without artificial flavoring-freedom from sugar alkalies and alcohol, no contraindications no oil leakage- no griping or pain no nausea or gastric disturbances not habit forming.

Next to constipation, fermentive diarrhea is a most frequent problem in summer, especially in children and the aged Thorough and regular elimination need consideration.

AGAROL

the original mineral oil and agar-agar emulsion with phenolphthalein, will prevent stasis, maintain normal elimination. No alkali, alcohol or sugar to cause difficulties And Agarol is so palatable that children take it gladly

POST GRADUATE COURSE IN KENTUCKY

The July issue of the *Kentucky Medical Journal* contains the following announcement of a two weeks post graduate course

'We are printing in this issue of the *Journal* the complete program for the Post Graduate Course to be held in Louisville from July 8th to 20th The course is held under the auspices of the Kentucky State Medical Association, and all of the doctors in the State, and, in fact, those of the neighboring states, as well as the Alumni of the University, will be cordially welcomed

'In addition to the regular program, arrangements have been made for special bedside work for small groups who are particularly interested in any line of work It is requested that those desiring this work register at the office at the City Hospital Headquarters The cost of the whole course is $1 00, which pays for registration and the certificate of attendance which is issued to those present

"This course offers a splendid opportunity of brushing up in the departments of medicine and surgery, and, besides, many old friendships are renewed, and new ones formed Those who took the course last year will be welcome again, as well as those to whom this will be the first time. Headquarters will be at the City Hospital, and the mail will also be cared for at that point

"Any further advice or information can be obtained from Dr Philip F Barbour, Chairman of the Post Graduate Course

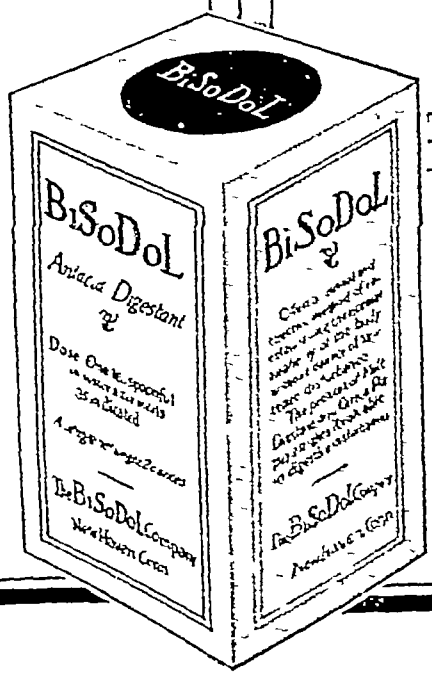
"Make this your summer vacation Louisville offers many attractions to the 'tired business man' A splendid stock company at the Brown Theatre shows all the latest Broadway successes for the moderate price of $1 00 for the best seats Privileges of four golf courses will be extended, through requests to members of these clubs, to all the physicians attending the school Louisville has two magnificent, free, open-air swimming pools, and the Y M C A will extend its privileges at a very modest sum All of the places of amusement have a cooling system, so that a pleasant evening can be enjoyed.

"The State Board of Health will open all its offices for the use of physicians, and the directors of all the departments will be at their desks each day for information and explanation of all the details of this work"

Leaves from a Therapeutic Notebook

Quickly Effective

THE keynote of the success of BiSoDoL as an effective alkalinizing agent is the Quick Relief that it affords in gastric hyperacidity



Such familiar symptoms as "sour stomach," eructations after meals, nausea and vomiting are quickly controlled by *the average dose of this* pleasantly flavored antacid.

BiSoDoL offers a balanced combination of the sodium and magnesium bases, together with bismuth subnitrate, digestives and flavorings

The same quick response follows the use of BiSoDoL in controlling the morning sickness of pregnancy, cyclic vomiting and the acidosis resulting from excessive alcoholism.

BiSoDoL is a prescription product It is not advertised to the public

PUBLIC RELATIONS COMMITTEE OF KANSAS

The July issue of the *Journal of the Kansas Medical Society* has the following editorial description of the publicity work of the State Medical Society

"Advertising is one form of publicity but there is a tendency on the part of certain groups to distinguish as advertising all forms of advertising that can be gotten free of cost

"It is unfortunately still true that a great many people acquire whatever information they have concerning diseases and their treatment from the advertisements in the newspapers We can not blame them The hundreds of dollars worth of junk accumulated in every doctor's office testifies to his credulity, to the readiness with which he accepts the advertised claims for things he has not thoroughly investigated Nor can the newspapers be blamed very much They have not been greatly encouraged to censor those advertisements very critically and have not been offered profitable material of a truthful character with which to fill the space Until within the last few years the exponents of scientific medicine have made no effort to advertise its work, and even now the publicity efforts are confined to those publications that donate the space This practically means the larger daily newspapers and a few popular magazines However, the people who depend mostly upon the local and county newspapers are the ones that get most of the misinformation from the uncensored advertisements referred to above, and it is to this class of people that our efforts should be largely directed

"There is a field for advertising in which the medical profession can be ethical, promote the service of scientific medicine, and help the people to a better understanding of diseases and their prevention and cure, and, what is more important at this time, can secure better cooperation with the newspapers

"For more than two years the Bureau of Public Relations of this society has been conducting a publicity campaign through the local and county newspapers of the state A considerable number of them have very generously published the articles sent them and there are excellent reasons to believe that with more encouragement from the medical profession in their particular localities they would take an active interest in an educational campaign along the lines suggested

"It is with this idea in view that the Bureau

preparing an advertising campaign to be conducted in cooperation with the county societies in the state. Full details of the plan and nature of the advertisements will be communicated to the secretaries of county societies in the near future"

THE ANNUAL MEETING OF THE MISSOURI MEDICAL ASSOCIATION

The July issue of the *Journal of the Missouri State Medical Association* held in Ozark, May 13-16, contains the following editorial criticisms on the way the sessions were conducted

"The officers of the Association are to be complimented upon the order displayed at the various sessions and the adherence to a strict time schedule This we feel is always conducive to a much more interesting session The ambulant or perambulant essayist may have matter of great worth to present, but only the few are possessed of sufficient power to hold the attention of an audience for very long periods of time, and so brevity added to the interest in the essays

"We still believe in and thoroughly approve of symposiums and we were justified in our opinion by the arrangement and character of those presented The interest of the members further justifies this belief There may be more satisfactory methods of presenting scientific material but we have not seen them

"One serious defect of this meeting, we think, was the almost complete absence of discussion of the scientific papers While we are thoroughly aware of the disadvantage of having too prolonged or too numerous discussions in a limited session, a moderate amount of discussion is of value as indicating a healthy interest on the part of the audience Absence of discussion may mean that the paper is not of such general interest that will admit of discussion, or that the audience is not interested enough to amplify the ideas expressed

"One more suggestion and our strictures end —the long scientific night sessions should be abandoned A few carefully selected papers would prove of greater interest and be more thoroughly absorbed The shorter program would permit of some diversions in the evenings"

SPECIAL DAYS FOR MEDICAL SOCIETIES

If the custom of setting aside certain days for special subjects keeps on growing, one's time will be ordered for a year in advance. The *Pennsylvania Medical Journal* for July records another day added to the two already set aside by the Pennsylvania State Society It says editorially

"Mental hygiene workers of Pennsylvania and elsewhere will be pleased to know that through the efforts of Dr Thomas G Simonton, the president of the State Medical Society, Mental Hygiene Day, like Cancer Day and Tuberculosis Day, has been placed in the annual program of the component county societies of the state. A great tripod, indeed, these three days, days around which the medical profession may center as it combats through prevention and curative measures three of mankind's most deadly foes

"That Dr Simonton sensed the feeling of organized medicine towards a strenuous campaign for the betterment of Pennsylvania's mentally ill, towards the need of further scientific studies and research, and towards the need of the individual physician fostering a better understanding of the mentally ill is manifested by the splendid cooperation of the county societies in putting on a Mental Hygiene Day program, the cooperation of state, municipal, and county institutions, and the cooperation of the Mental Hygiene Committee of the Public Charities Association

"It is not difficult to visualize the far-reaching results of the progressive step of Dr Simonton, for in the last analysis it is the physician, the nurse, and organized medicine to whom the rank and file look for guidance and instruction More power to organized medicine in keeping always Mental Hygiene Day, Cancer Day, and Tuberculosis Day before its members!"

If pure water is important to people in good health, how much more essential it is to invalids.

KNOX IN DIABETES

One of the problems in diabetes is to keep the patient diet-happy! And Knox Sparkling Gelatine can be of real service.

Knox Gelatine combines perfectly with the foods prescribed for the diabetic diet. It makes dishes that are appetizing and *different* to the eye and the taste. It supplies the diet variety that satisfies the patient's appetite and it supplies the food-bulk that the patient's hunger craves

People suffering from diabetes really enjoy gelatine dishes—and they *can* enjoy them if they have our diabetic recipes, prepared by one of the country's recognized dietitians Remember, Knox Gelatine is free from *sugar*—See page XV —*Adv*

CREST VIEW SANATORIUM

Charmingly located, beautifully appointed, in the hilly country one and a half miles from Long Island Sound where the air is tonic. Quick drive from New York City Truly homelike, no institutional appearance.—See page XXIX —*Adv*

Z B T BABY TALCUM

Scientifically prepared according to the formula of an internationally known pediatrician Free from lime or other harmful irritants Endorsed by leading physicians, nurses and hospitals Sold by druggists everywhere. See page XX —*Adv*

ROBINSON'S "PATENT" BARLEY & GROATS

These two old established preparations have held the confidence of the Medical Profession for years The Barley is mainly employed in infant dietetics, and for the quick preparation of pure Barley Water Robinson's Groats are largely recommended in conjunction with cow's milk for weaned infants, expectant and nursing mothers, and as an invalid diet.—See page XIX —*Adv*

AGAROL

Agarol contains no sugar—safe in diabetes, no alkali—does not interfere with digestion, no excess of oil—to cause leakage. Just the right proportion of ingredients to afford these desirable actions Softening of the intestinal contents, gentle stimulation of the peristaltic function.—See page XXI.—*Adv*

MEAD'S DEXTRI-MALTOSE

Mead's Dextri-Maltose, cow's milk and water can, with but few exceptions, be relied upon for good results in artificial feeding cases

The addition of Dextri-Maltose makes up the carbohydrate deficiency in the cow's milk. It is easily assimilated—well tolerated.

Gains in weight are usually normal, presenting a healthy clinical picture—sound musculature—good color

There is a minimum of nutritional disturbances of a fermentative nature due to the greater assimilation limits of Dextri-Maltose over either lactose or sucrose.

Dextri-Maltose No 1 is indicated for normal infants, while the No. 3 with 3% addition of potassium bicarbonate, is the clinical choice if calcium constipation is present—See pages II—XXXII —*Adv*

AURORA HEALTH FARM

A new addition to the AURORA HEALTH FARM has just been completed, and this time it is an altogether modern building with elevator service from basement to roof, private bath and telephone in each room, a large, sunny dining room overlooking a magnificent panoramic view of the surrounding hills, a beautiful big lobby with adjoining

OXYGEN THERAPY IN PNEUMONIA*

By ALVAN L BARACH, M D, NEW YORK, N Y

THE therapeutic use of oxygen began in the year 1917 when two distinguished physiologists, Haldane (1) and Meltzer (2), observed that favorable results followed its effective administration The history of the employment of oxygen prior to this time may be disregarded since it was given haphazardly or in insufficient concentrations Haldane devised a face mask which was successfully used in cases of pulmonary edema due to war gas poisoning Meltzer treated patients with pneumonia with an oral insufflation apparatus and reported marked improvement in some cases As a result of the beneficial effects of adequate oxygen therapy reported by these two physiologists, an impetus was given to the use of oxygen in clinical disease In the next 12 years the physiologic principles of oxygen want were reviewed and effective methods of administering oxygen brought to the clinic for the first time.

The physiologic basis for the therapeutic use of oxygen rests on three sets of evidence

(1) The harmful effects of acute oxygen-want were demonstrated by the symptoms of mountain-sickness and by laboratory experiments in closed chambers in which the air was artificially deprived of oxygen Among these effects were cyanosis, rapid pulse rate, disturbances in breathing, nausea and vomiting, slight fever, fatigue, delirium, and finally collapse. (Barcroft (3), Haldane (4) and others)

(2) By means of the arterial puncture (Hurter (5) and Stadie (6)) and accurate methods of blood gas analysis (Van Slyke (7) and Haldane (8)), it was shown that the arterial blood of patients with pneumonia at times contained a markedly diminished oxygen content The degree of arterial oxygen unsaturation found in pneumonia was frequently as severe as that which experimentally induced the symptoms noted above

(3) The administration of 40 to 60 per cent oxygen to pneumonia patients suffering from acute anoxemia raised the oxygen saturation of the arterial blood to or near the normal value. (Meakins (9), Stadie (10), Barach (11), Binger (12))

(From the Department of Medicine, Columbia University College of Physicians and Surgeons and the Presbyterian Hospital.)

During this period, approximately 400 cases of pneumonia have been reported in the literature which have received adequate oxygen therapy We wish to present tonight 100 cases of pneumonia treated in an oxygen chamber or oxygen tent during the past 2 years The apparatus employed has been described in other communications We will mention here merely that the tent consists of a square hood placed on the head and chest of the patient, with a closed system of ventilation in which the air is cooled and dried by direct passage over ice (13)

The chamber consists of a large room which is ventilated by convection currents set up by a system of brine pipes on one side of the room and a steam radiator on the other side, both enclosed so as not to be visible to the eye (14) No motors, pumps or fans are used in this chamber (see accompanying illustration)

The humidity and temperature of the air in the room may be independently controlled

This group of cases comprises the severest examples of pneumonia seen in hospital or private practise. The patients were generally selected because a decided turn for the worse had taken place in their clinical course Cyanosis was uniformly present Mortality figures on routine cases admitted to hospitals are thus not applicable to this group In some instances, as will be seen, the patient died 4 to 12 hours after oxygen therapy was begun, a circumstance which illustrates the gravity of the condition of the patient for whom oxygen therapy was recommended The mortality rate of the 100 cases was 45 per cent

In the effort to determine the expected mortality of a group of this character we have made use of the figures of Stadie (6) in his original series of pneumonia patients not treated with oxygen In our cases cyanosis has been recorded in plus signs, + corresponding to 80 to 85 per cent arterial oxygen saturation, ++ to 75 to 80 per cent, +++ to 65 to 75 per cent, ++++ below 65 per cent The mortality of his series of 32 patients (7 lobar and 25 post-influenzal bronchopneumonia) was 12 per cent for those who had little or no cyanosis (above 80 per cent arterial

oxygen saturation) and 93 per cent for those who had moderate severe cyanosis (below 80 per cent arterial oxygen saturation)

In a recent series of 130 patients with pneumonia reported by Binger (12), a positive correlation also existed between anoxemia and mortality Many of these cases were treated in the oxygen chamber so that they can not be used as a control group However, including observations on patients during the acute stage of the disease irrespective of any therapeusis, the results are a striking confirmation of the finding of Stadie that a higher mortality is associated with oxygen want in pneumonia The mortality of 48 patients having an arterial oxygen saturation below 80 per cent was 56 per cent, whereas the mortality of 83 patients with an arterial oxygen saturation above 80 per cent was 24 per cent

Our treated cases who had an anoxemia approximately comparable to the group below 80 per cent arterial oxygen saturation had a mortality of 45 per cent Before concluding that oxygen therapy has decidedly lowered the death rate we wish to present an analysis of the fatal and recovered cases on the basis of the factors which independently modify the rate of mortality in pneumonia Table 1 and Table 2 present the complete data on the fatal and recovered groups The subsidiary tables follow

TABLE 3

Data on Sputum Organism in Fatal and Recovered Cases

	Sputum Organism				
	Pn I	Pn II	Pn III	Pn IV	Miscellaneous Untyped
Fatal Cases	7	2	13	7	15
Recovered Cases	8	3	3	20	21

The influence of the type of organism in the sputum on mortality is represented in this series (Table 3) by the large proportion of pneumococcus type III in the fatal cases (13 deaths and 3 survivals) In the pneumococcus type IV group there were 7 deaths and 20 recovered cases The mortality rate in type III pneumonia was 81 per cent, in type IV 26 per cent

TABLE 4

Data on Blood Cultures of Fatal and Recovered Cases

	Blood Culture		
	Sterile	Positive	Positive %
Fatal Cases	15	13	46 4
Recovered Cases	24	5	17 2

The data on blood cultures in the fatal and recovered cases (table 4) bears out the opinion that a blood stream infection is more apt to be associated with a fatal outcome 46 per cent of the fatal cases and 17 per cent of the recovered cases had a positive blood culture (In this series blood cultures were taken as a part of the routine work-up of the patient, from one to three times during the course of the illness More frequent blood cultures yield a higher percentage of positive results without changing appreciably the contrast in the two groups) All cases of type III bacteremia (6 in number) died In our experience the presence of pneumococcus type III organism in the blood late in the disease is a very grave prognostic sign

TABLE 5

Data on Age Groups of Fatal and Recovered Cases

	Number of Patients in Ages			
	Up to 20	20 to 40	40 to 60	60 to 80
Fatal Cases	3	11	22	9
Recovered Cases	14	19	17	5

The effect of age on mortality rate is evident in table 5 The proportion of fatal cases shows a consistent increase as the age group is advanced The mortality rate of all patients under 40 years was 29 8 per cent, over 40 years 58 5 per cent.

The influence of the above factors has been pointed out by previous observers, and is clearly shown in the larger series of Cecil (15)

TABLE 6

Data on (1) Day of Disease Oxygen Therapy was commenced and (2) Length of Residence in Tent or Chamber

	Day of disease O_2 was begun*	Length of residence in chamber or tent‡
Fatal Cases	6 5	2 5
Recovered Cases	4 6	6 0

*Based on an analysis of 24 fatal cases and 21 recovered cases

‡Excluding Case No 57, who was in a tent 61 days

In table 6 the day of disease on which oxygen therapy was begun and the length of residence in the chamber or tent is shown in both groups of cases In the fatal cases oxygen therapy was commenced 6 5 days after onset of disease, in the recovered cases 4 6 days The fatal cases lived 2 5 days in the chamber or tent, the recovered cases 6 0 days There were 17 patients who died a day or a fraction of a day after oxygen therapy was begun It is evident firstly that these patients were generally selected late in the disease, and secondly, that the later oxygen therapy was begun the higher the rate of mortality It is also apparent that many of them were so desperately ill as to survive only 4 to 24 hours after treatment was instituted

These figures show in the first place that oxygen therapy in this series has not profoundly altered the factors known to influence the rate of mortality in pneumonia Thus, the presence of type III in the sputum, bacteriemia late in the disease, old age, and late treatment are associated with a high mortality in oxygen treated cases as well as in non-oxygen treated cases The limitations of oxygen therapy are thus revealed In the second place, it indicates that no statistical evaluation of oxygen treatment can be made until a similar group of untreated cases is recorded from the same point of view By this we mean that similar age groups must be compared suffering from the same type of organism, treated on the same day of disease In the age group above 40 years the mortality rate was twice as great as in the age group below 40 years In type III pneumonia, the mortality rate was three times as great as in type IV A control series must therefor be specifically controlled in all the factors mentioned above, before conclusions may be drawn concerning the therapeutic value of a remedy for pneumonia For this reason we believe we are not justified (statistically) in concluding that we have lowered the mortality rate of severe cyanotic pneumonia even though the mortality in the untreated series of Stadie was 93 per cent, and in the partly treated series of Binger 56 per cent. The same criticism is applicable to any investigation which bases its results on a statistical evaluation of mortality rate in pneumonia

It is, however, our impression from an analysis of the material here presented and from watching the patients themselves that a higher mortality would have obtained in the absence of oxygen treatment Personal observation provided it is unprejudiced cannot be entirely disregarded because it lacks the capacity for statistical proof

The alteration in the symptomotology of this group of patients after the administration of oxygen has shown a contrast between the fatal and the recovered cases Disappearance or diminution of cyanosis, slowing of the pulse rate, and increased comfort of the patient were more marked in the recovered group Slowing of the respiratory rate, decreased dyspnea, lessening of delirium, and a lowering of the temperature were also observed, although less consistently in both groups We wish to report a case in detail which supports our belief that life is at times prolonged by oxygen therapy

Case 1—Male, Age 48 Past History Patient has had asthma since a child of 6 years with winter attacks of bronchitis He had pneumonia five times in the past 6 years Present illness began with a cold which was treated with chlorine inhalation, concentration not known Three days after the chlorine treatment, patient was worse, suffering from persistent cough, malaise, fever of 101 6 Six days later he definitely had pneumonia A portable X-ray picture showed spotty infiltration of the R L L with pleuritic adhesions at the bases He became progressively worse during the following 8 days when his condition finally was desperate He was markedly cyanotic and dyspnoeic, delirious, temperature 104.2, pulse 140, weak, thready, small, respiratory rate 40 Examination of the lungs revealed scattered crepitant rales throughout, especially over the lower two-thirds of both chests posteriorly Dullness and diminished breath sounds were present at both bases In scattered areas in the R L L the breath sounds had a bronchial character Sputum contained pneumococcus type III and numerous influenza bacilli Blood culture was sterile White blood cells numbered 32,000, Polynuclears 83 per cent, Hemoglobin 77 per cent, red blood cells 4,220,000

He was put in the oxygen tent, oxygen concentration 55 per cent On the following day he was much improved, temperature 102 0, pulse 114, respirations 28. Cyanosis was markedly diminished

During the next four days he continued to run an elevated pulse temperature, and respiration, but was fairly comfortable in the tent He was taken out of the tent for one-half hour but had to be put back due to the quick onset of cyanosis, elevated pulse and respiration A portable X-ray picture revealed a most extensive infiltration of both lungs, consisting of large areas of infiltration, most of them discretely separated off, some of them confluent. On the following two days he was taken out for one-half hour, again with symptoms of acute anoxemia The next day he was kept out on an order for one and one-half hours, at the end of which time he was in a state of collapse, deeply cyanotic, dyspnoeic, pulse 140, small and thready After administration of caffein sodium benzoate and return to the tent, he gradually returned to his previous condition

During the next two weeks little change occurred except that the signs in the lungs seemed a little less marked Temperature was intermittent in character, between 101 6 and 103 6, pulse between 106 and 120, respiration 28 to 36 At times one part of the lung would clear, his general condition would seem definitely better, when a new shower of crepitant rales with later a bronchial character to the breath sounds would appear The oxygen concentration was lowered to 40 per cent On the 24th and 25th day of disease, he was out of the tent for three hours before rising pulse and respiration compelled re-entry into the tent On the 27th, 28th 29th days he was kept out 8 to 16 hours, but his condition definitely became worse, with higher temperature, pulse and respiration On the 31st day he was kept out four hours, at the end of which time he was cyanotic and dyspneic, temperature rising from 101 to 105 The attempt to remove him from the tent was abandoned until the lungs showed a substantial clearing on physical examination Because of the per-

sistence of type III in the sputum, subcutaneous vaccination was instituted He was given types I, II, III pneumococci, the latter prepared from his sputum During the next 20 days he received four courses, approximately at 5 day intervals, aggregating 10 billion organisms of each type (A mixed stock vaccine including the influenza bacillus was also administered although without any real belief in its power to arouse an immunological response against the influenza organism) At the end of the first week there was slight protection against type III pneumococcus, the second week against I and III, the third week against I, II and III On the 42nd day of residence in the tent, a portable X-ray showed a moderate diminution of involvement, but scattered large areas of infiltration were still present The oxygen concentration was lowered to 35 per cent, occasionally returning to 40 per cent On the 61st day, he was definitely better, temperature 100 to 101, pulse 94

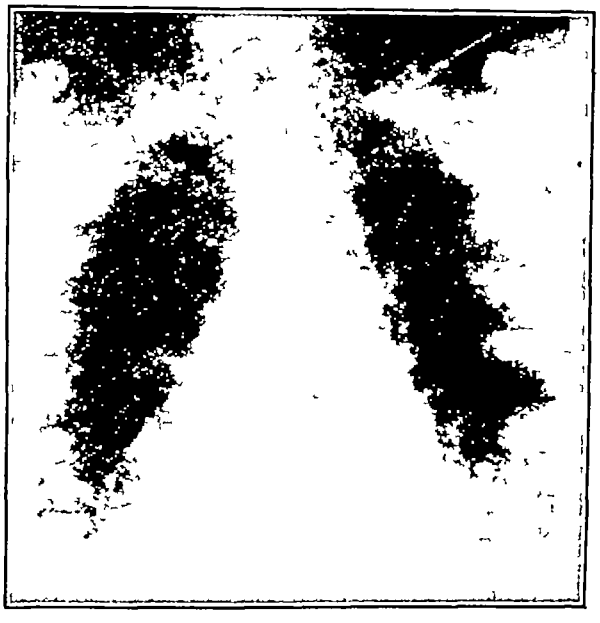

FIG 1 *X-Ray Onset of Pneumonia*

to 114, respiration 32 to 38 The lungs were clearer, with fewer rales and no bronchial breathing He was taken out of the tent without definite change in his condition On the following four days he was put in the tent irregularly for two to four hours without perceptible change in pulse, respiration or temperature, and oxygen treatment was stopped A low grade fever continued for one month after, when it became continuously normal He gradually became rational, regained his strength, and went to the country The lungs had cleared except for numerous crepitant rales at both bases (The author wishes to express his appreciation for the opportunity to use the material here presented to Dr Walter G Lough, who was the physician in charge of the patient and to

FIG 2 *Four days after Oxygen Treatment was applied*

Dr Marcus Rothschild who served as consultant)

SUMMARY

A series of 100 patients with pneumonia are reported who have been treated in an oxygen tent or oxygen chamber The group was characterized by the uniform presence of cyanosis, a generally critical condition of the patient and the application of treatment late in the disease An analysis of the fatal and recovered cases shows that the factors known to modify pneumonia mortality exert their influence in this series, namely, age of the patient, type of sputum organism, bac-

FIG 3 *42nd Day of Residence in Tent*

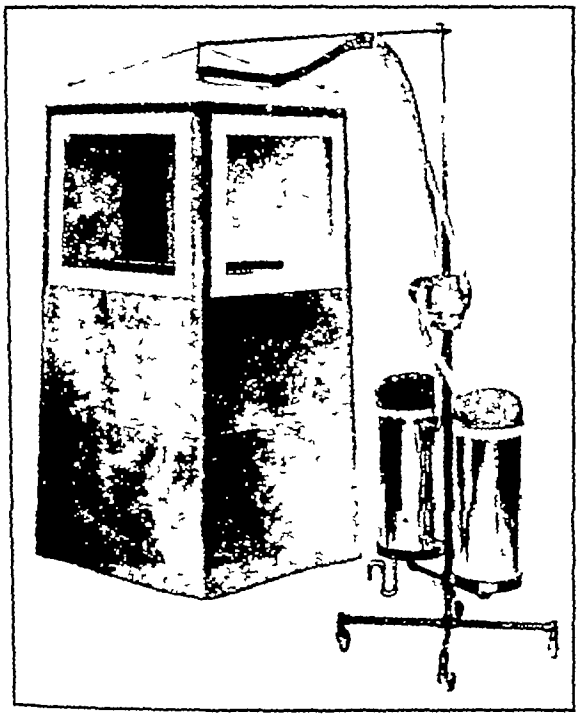

FIG 4 *Oxygen Tent*

teremia and day of disease treatment is instituted To this extent the limitations of oxygen therapy are revealed Comparison of the mortality in this series to that of a group of untreated cyanotic pneumonia patients and a group of partly treated cyanotic patients shows a decided decrease in the oxygen-treated series The absence, however, of untreated cases properly controlled in respect to the factors which of themselves influence pneumonia mortality prevents any conclusions of a statistical nature being drawn The inference that a higher mortality would have obtained in the absence of oxygen therapy appears justified on the basis of personal observation and an analysis of the assembled material

The beneficial effects of oxygen therapy in individual cases are presented One patient who lived in an oxygen tent for two months is reported in detail in whom oxygen appeared to prolong life until the patient finally developed an immunologic resistance to the disease

TABLE 1 DATA ON FATAL CASES OF PNEUMONIA TREATED IN OXYGEN CHAMBER OR OXYGEN TENT

Case No	Age	Diagnosis	Lobes Involved	Sputum Organism	Blood Culture	Days in Tent	Cyanosis		REMARKS
							Before O2	After O2	
1	53 yrs.	Lobar Pneumonia	R.L.L L.L.L.	PN I	–	5	+++	0	Patient did well for 4 days, when cardiac failure and pulmonary edema supervened
2	38 yrs.	Lobar Pneumonia	R.L.L.	PN I	Sterile	5	++	0	Lessened cyanosis. No effect on pulse, dyspnea or comfort.
3	40 yrs.	Lobar Pneumonia	R.L.L. L.L.L	PN I	PN I	1	+++	+	Diminished cyanosis No effect on pulse Marked prostration.
4	59 yrs	Bronchopneumonia Cardiac hypertrophy	R.L.L. L.L.L.	PN I	PN I	3	+	0	Improved pulse.
5	27 yrs	Lobar Pneumonia Edema of Lungs	R.L.L L.L.L	PN I	PN I	1	+++	+	No improvement except lessened cyanosis Old man with marked pulmonary edema
6	37 yrs	Lobar Pneumonia	L.U.L. L.L.L	PN I	Sterile	1 2/3	++	+	No improvement except lessened cyanosis. Developed edema of lung after operation
7	40 yrs.	Lobar Pneumonia Empyema	R.L.L L.L.L	PN I	PN I	7	++	0	Was in excellent condition until development of empyema Died after serum injection on 9th day
8	23 yrs.	Lobar Pneumonia	R.L.L. R.M.L. R.U.L.	PN II	Sterile	1/2	+++	++	No improvement. Pulse 140
9	40 yrs.	Lobar Pneumonia Mitral Stenosis Cardiac Hypertrophy and Dilatation Cardiac Insufficiency	R.L.L. R.M.L. R.U.L.	PN II	PN II	2	+++	++	Patient jaundiced heart felt to axilla, appeared moribund Responded to treatment for 2 days, died of heart failure
10	45 yrs	Lobar Pneumonia Hypertension Arteriosclerosis	R.L.L. L.L.L.	PN III	Sterile	1/3	+++	++	Pulse 148 respiration 44 when put in chamber Arterial oxygen saturation 47%
11	30 yrs	Lobar Pneumonia	R.L.L. L.L.L	PN III	B Influenza	2	+++	++	Marked cyanosis and dyspnea. Diminished after entering chamber
12	50 yrs.	Lobar Pneumonia Edema of Lungs chronic Myocarditis, Chronic Pulmonary Tuberculosis	R.L.L R.U.L.	PN III	Sterile	1½	+++	0	Cyanosis disappeared pulse slowed in oxygen chamber Appeared more comfortable until edema of lungs became widespread
13	60 yrs	Lobar Pneumonia Chronic Myocarditis Arteriosclerosis	R.L.L. R.U.L	PN III	Sterile	1½	++	++	No improvement noted Temperature became normal. Pulse, respiration and cyanosis increased
14	45 yrs	Lobar Pneumonia Edema of Lungs	R.U.L L.L.L	PN III	–	1	+++	++	Edema of lungs. No improvement.
15	46 yrs	Lobar Pneumonia (Post-operative) Carcinoma of Female Mammary Gland Edema of Lungs	R.L.L L.L.L	PN III	PN III	3	+++	+	Widespread pulmonary edema. Subjective and objective improvement
16	41 yrs	Lobar Pneumonia	R.U.L. R.M.L. R.L.L	PN III	PN III	1/6	+++	++	No improvement
17	70 yrs	Lobar Pneumonia	R.L.L R.U.L	PN III	–	1	++	+	Temporary improvement in color and pulse.
18	50 yrs	Lobar Pneumonia Edema of Lungs	R.L.L. L.L.L	PN III	PN III	1¼	+	0	Arterial oxygen 83 2% before using tent 90 0% after
19	34 yrs	Lobar Pneumonia	R.L.L. L.L.L.	PN III	PN III	2	+++	+	Color comfort and pulse improved temporarily on first day Died of pulmonary edema.

TABLE I DATA ON FATAL CASES OF PNEUMONIA TREATED IN OXYGEN CHAMBER OR OXYGEN TENT

Case No	Age	Diagnosis	Lobes Involved	Sputum Organism	Blood Culture	Days in Tent	Cyanosis		REMARKS
							Before O2	After O2	
6	32 yrs	Lobar Pneumonia	R L L L L L	PN III	PN III	3	+++	+	Severely toxic prostrated Color improved, seemed more comfortable
21	48 yrs	Lobar Pneumonia	R L L R U L L L L	PN III	PN III	4	+++	++	Very prostrated and toxic. Much improved in 40% oxygen for 2 days Blood culture showed Type III on three examinations
22	51 yrs.	Lobar Pneumonia General Arteriosclerosis	R L L L L L	PN III	Sterile	3	+++	0	Distinct improvement in color, pulse and comfort. Died suddenly when apparently getting well
23	52 yrs	Confluent Broncho-pneumonia; Acute Endo-carditis Suppurative Pleurisy, Arteriosclerosis	Diffuse Process	PN IV	Sterile	5	+++	+	Temporary improvement. Cyanosis diminished
24	41 yrs	Lobar Pneumonia Edema of Lungs	R I L	PN IV	Sterile	1/4	++	+	No improvement
25	78 yrs.	Lobar Pneumonia, Arteriosclerosis (General and Coronary), Fibrosis of Myocardium Edema of Lungs Cardiac Premature Contractions	L I L R U L R R L	PN IV	Sterile	1/4	+++	+	Widespread edema Color improved but labored breathing continued
26	59 yrs	Lobar Pneumonia Edema of Lungs	L U L R U I R M L R L I	PN IV	Sterile	2	++	0	Patient was better, collapse followed opening of oxygen chamber for 2 hours
27	23 yrs	Influenza Bronchopneumonia	R L L. L L L	PN IV Strepto-coccus	–	4	++	0	Patient s color and pulse distinctly better after 12 hours in oxygen Tem perature was normal in 4 days Patient suddenly died 1 week later apparently due to embolus
28	49 yrs.	Acute Pulmonary Tuber culosis, Lobar Pneumonia	R L L. L L L.	PN IV	Sterile	7	+++	+	Marked improvement in comfort, color and pulse, with temporary recovery, followed by flare-up of tuberculosis and cardiac collapse
29	42 yrs.	Lobar Pneumonia	R L L L L L.	PN IV	Sterile	4	+++	+	Marked improvement in color; slight improvement in pulse
30	50 yrs	Cholecystectomy, Bronchopneumonia, Atelectasis of Lung	L L L	Influenza Bacillus	Sterile	6	++	0	Temporary improvement in color and pulse.
31	20 yrs.	Typhoid Fever, Tuberculosis (Chronic and Acute) Bronchopneumonia	R L L L L L	Tubercle Bacillus	Typhoid	7	++	+	Temporary improvement in color and pulse.
32	65 yrs	Bronchopneumonia Edema of Lungs	R L L	–	–	1/2	+++	+	No improvement except lessened cyanosis. Old man with marked pul monary edema
33	65 yrs	Lobar Pneumonia	R L L. R U L.	–	–	1 6	+++	++	No improvement
34	60 yrs.	Lobar Pneumonia Chronic Alcoholism	R L L L L L.	–	–	2	+++	+	Temporary improvement in color pulse and breathing
35	58 yrs.	Lobar Pneumonia	R L L L L L.	–	–	1/3	+++	+	No improvement, excepting diminished cyanosis.
36	14 yrs	Lobar Pneumonia	R L L L L L R U L	–	–	1½	+++	+	Four attacks of pneumonia Response to oxygen shown by slower pulse and respiration in oxygen than out of tent.
37	76 yrs.	Lobar Pneumonia, General Arteriosclerosis, Edema of Lungs	R L L L L L	–	–	6	++	0	Pulse lower in oxygen. Respirations unaffected Appeared better, but suddenly collapsed

TABLE 1 DATA ON FATAL CASES OF PNEUMONIA TREATED IN OXYGEN CHAMBER OR OXYGEN TENT

Case No	Age	Diagnosis	Lobes Involved	Sputum Organism	Blood Culture	Days in Tent	Cyanosis		REMARKS
							Before O_2	After O_2	
38	51 yrs	Bronchitis Abscess of Lung, Pyopneumothorax, Pulmonary Emphysema, Bronchopneumonia chronic Myocarditis	Diffuse Process	Gram Positive Cocci	Sterile	1	+++	+	Patient was in oxygen tent 6 days When removed, he collapsed with rising pulse and respiration After transfer to chamber he recovered, but later developed pneumothorax.
39	15 mths	Bronchopneumonia, Rickets, Secondary Anemia, Marasmus	Diffuse Process	–	–	3	++	+	No improvement
40	23 yrs	Bronchopneumonia, Secondary Anemia	R.U.L R.L.L R.M.L	–	–	1	0	0	Hemoglobin was 35% No improvement
41	4 wks	Bronchopneumonia	R.L.L. L.L.L	–	–	4	++	0	Cyanosis at birth in premature 8-month infant. Occurring in attacks, cause unknown. Developed pneumonia 3 weeks later Cyanosis relieved by oxygen
42	70 yrs	Prostatectomy, Bronchopneumonia	R.L.L.	–	–	1	+	0	Collapse following prostatectomy, with secondary bronchopneumonia
43	50 yrs	Bronchopneumonia, Edema of Lungs	L.L.L	–	–	½	+++	+	Old woman developed edema of lungs after operation. Decreased cyanosis
44	36 yrs	Pregnancy, Lobar Pneumonia Edema of Lungs	R.L.L	–	–	1	+++	+	Terribly prostrated pneumonia after delivery of healthy infant Color and pulse improved
45	60 yrs	Lobar Pneumonia	R.L.L. L.L.L.	–	–	2	+	0	Pulse thready when tent was applied Became fuller 2 hours later, but subsequently became worse

TABLE 2. DATA ON RECOVERED CASES OF PNEUMONIA TREATED IN OXYGEN CHAMBER OR OXYGEN TENT

Case No	Age	Diagnosis	Lobes Involved	Sputum Organism	Blood Culture	Days in Tent	Cyanosis		REMARKS
							Before O_2	After O_2	
46	35 yrs	Lobar Pneumonia	R.L.L. L.L.L.	PN I	Sterile	4	++	0	Improvement in color and comfort.
47	35 yrs	Lobar Pneumonia	L.L.L. R.L.L.	PN I	PN I	4	++	0	Pulse and respiration slower in tent.
48	44 yrs	Lobar Pneumonia	R.L.L L.L.L	PN I	PN I	3	+++	0	Patient more comfortable, pulse slower, respiration unchanged
49	43 yrs	Bronchopneumonia	R.L.L.	PN I	PN I	4	+	0	More comfortable, less dyspnea pulse unchanged
50	16 yrs.	Lobar Pneumonia	L.L.L R.L.L	PN I	Sterile	4	+++	0	Arterial oxygen saturation raised from 66 0 to 89 6% Pulse and respiration slowed
51	28 yrs	Lobar Pneumonia Edema of Lungs	R.L.L L.L.L R.M.L	PN I	PN I	2	+++	0	Had oxygen with rebreathing apparatus three days before. Arterial oxygen saturation 73 8 to 90 2% Striking improvement in pulse, color and breathing
52	58 yrs	Lobar Pneumonia	R.L.L	PN I	–	4	++	0	Marked subjective relief Disappearance of cyanosis
53	40 yrs	Lobar Pneumonia	R.L.L L.L.L	PN I	–	2	++	+	Diminished cyanosis
54	20 yrs.	Lobar Pneumonia	L.U.L. R.L.L	PN II	PN II	1	++	0	Color pulse and breathing improved after transfer to oxygen chamber

TABLE 2 DATA ON RECOVERED CASES OF PNEUMONIA TREATED IN OXYGEN CHAMBER OR OXYGEN TENT

Case No	Age	Diagnosis	Lobes Involved	Sputum Organism	Blood Culture	Days in Tent	Cyanosis		REMARKS
							Before O2	After O2	
55	17 yrs	Lobar Pneumonia Aortic insufficiency Cardiac hypertrophy and insufficiency	R L L L L L R M L	PN II	—	11	+++	+	Cyanosis diminished Patient appeared more comfortable Pulse improved
56	20 yrs	Lobar Pneumonia	R L L R M L R U L L L L	PN II	Sterile	4	+++	0	Temperature, pulse and respiration became less in oxygen Objected to tent.
57	48 yrs	Bronchopneumonia	R L L L L L R U L L U L	PN III	Sterile	61	+++	0	Marked improvement in color, volume and rate of pulse and comfort of patient
58	46 yrs	Bronchopneumonia	R L L	PN III	—	3	++	0	Relief of cyanosis Pulse slower and fuller Pneumonia appeared after overdose of veronal.
59	39 yrs	Lobar Pneumonia	R L I R U L	PN III	Sterile	5	+++	+	Color and general appearance better in oxygen chamber
60	42 yrs	Lobar Pneumonia	R L L L L L	PN IV	—	9	+++	0	Marked improvement in color and general appearance Pulse slower Subjective relief
61	38 yrs	Lobar Pneumonia	R L L L L L	PN IV	—	4	+++	+	Marked improvement in color
62	58 yrs	Asthma Broncho-pneumonia	L L L	PN IV	Sterile	4	++	0	Pulse slower and fuller, no relief of dyspnea Patient fought tent.
63	30 yrs	Bronchopneumonia	R L L	PN IV	Sterile	11	++	0	Marked subjective relief Infarct of lung appeared 10 days after operation followed by consolidation of entire right lower lobe
64	40 yrs	Post-operative Broncho-pneumonia	R L L	PN IV	Sterile	3	+++	+	Marked improvement in color and pulse
65	65 yrs	Lobar Pneumonia	R L L	PN IV	—	5	++	0	No definite change observed except improved color
66	30 yrs	Post-operative Lobar Pneumonia	R L L	PN IV	Sterile	6	++	0	Pulse slower, color better in tent. Seemed comfortable
67	25 yrs	Lobar Pneumonia	R L L	PN IV	—	4	++	0	Diminished cyanosis Patient did not like being in tent No change in pulse
68	41 yrs	Bronchopneumonia	R L L	PN IV	Sterile	5	+++	+	Marked relief of color and comfort Improved pulse after oxygen
69	30 yrs.	Influenza, Bronchopneumonia	R L L	PN IV	Sterile	4	+++	+	Marked improvement in color and pulse Patient did not like tent
70	45 yrs	Splenic anemia Bronchopneumonia	R L L	PN IV	—	5	0	0	Severe anemia Hemoglobin 20% Pulse and comfort markedly improved
71	43 yrs	Bronchopneumonia	Diffuse Both Lungs	PN IV	Sterile	7	++	0	Patient enjoyed tent, pulse slower, dyspnea less
72	28 yrs.	Lobar Pneumonia	R L L L L L	PN IV	—	5	++	0	Striking improvement in volume and rate of pulse Very comfortable
73	41 yrs	Lobar Pneumonia Edema of Lungs	L U L L L L	PN IV	Sterile	5	++++	+	Definite improvement subjectively after entering tent Had widespread pulmonary edema.
74	13 yrs	Lobar Pneumonia	R L L R U L	PN IV	Sterile	4	+++	+	Definite pluse slowing after removal to chamber
75	19 yrs	Lobar Pneumonia	R L L L L L	PN IV	Sterile	3	+++	+	Marked improvement after transfer to chamber in color, slowing of pulse and dyspnea

TABLE 2 DATA ON RECOVERED CASES OF PNEUMONIA TREATED IN OXYGEN CHAMBER OR OXYGEN TENT

Case No	Age	Diagnosis	Lobes Involved	Sputum Organism	Blood Culture	Days in Tent	Cyanosis		REMARKS
							Before O2	After O2	
76	44 yrs	Lobar Pneumonia Chronic Alcoholism Syphilis	L U L L L L	PN IV	Sterile	3	+++	0	Had hyoscin collapse with respiratory failure relieved by breathing 10% CO2 and 90% oxygen
77	14 yrs	Lobar Pneumonia Suppurative Pleurisy (Right and Left Chest), Pelvic Peritonitis Subphrenic abscess	R L L L L L	Strept-ococcus	Sterile	21	++	0	Striking improvement in dyspnea, cyanosis and pulse which dropped from 168 to 130 in 4 hours Marked subjective relief
78	30 yrs	Lobar Pneumonia	R L L L L L	PN IV	Sterile	5	++++	+	Patient seemed moribund very cyanotic Marked relief of cyanosis, dyspnea and slowing of pulse Marked subjective relief
79	8 yrs	Bronchopneumonia	Diffuse Both Lungs	—	—	14	++	0	Marked improvement in color, pulse and comfort
80	12 yrs	Gun shot wound of chest Bronchopneumonia	L L L	—	—	3	+++	+	Marked improvement in dyspnea, color, comfort and pulse
81	58 yrs	Lobar Pneumonia	R L L	—	—	6	++	0	Patient was jaundiced throughout the attack Comfortable in tent
82	05 yrs.	Lobar Pneumonia	R L L L L L	—	—	4	++	0	Pulse fuller and slower Comfortable in tent
83	04 yrs.	Lobar Pneumonia	R L L	—	—	6	++	0	More comfortable in tent. Pulse fuller and slower
84	2 yrs	Whooping Cough Measles Broncho-pneumonia	Diffuse Both Lungs	—	—	14	++	0	Patient quiet and comfortable in tent, slept better, cyanosis completely relieved
85	1 wk.	Atelectasis of Lungs	R L L L L L	—	—	1	++	0	Cyanosis at birth in premature 8-month infant, occurring in attacks Cause unknown
86	7 yrs	Bronchial Stenosis Bronchopneumonia	R L L	—	—	7	++	+	Following a sore throat, intermittent bronchial stenosis developed, relieved by bronchoscopic suction
87	1 day	Atelectasis of Lungs	R L L L L L	—	—	0	+++	0	Chest barely moved on inspiration apparently due to atelectasis of both lungs Under 50% oxygen color was good, in 3 days lungs began to expand
88	26 yrs	Bronchopneumonia	L L L.	Strept ococcus	Sterile	5	++	0	Comfort, color and pulse better in tent.
89	22 yrs	Lobar Pneumonia	L L L	—	Sterile	4	+	0	More comfortable in oxygen environment, partly due to coolness of air
90	23 yrs	Lobar Pneumonia	R L L	—	Sterile	3	++	0	Improved pulse
91	3 yrs.	Bronchopneumonia	Both Lungs	—	Sterile	28	+++	+	Patient was extremely ill Pulse dropped from 190 to 160, respiration from 85 to 75, and color cleared 2 hours after she was put in tent
92	38 yrs	Lobar Pneumonia	R L L L L L	PN IV	Sterile	4	++	0	Subjective relief noticed Pulse and temperature lower 12 hours after put in tent.
93	26 yrs	Lobar Pneumonia Edema of Lungs	R L L L L L	—	—	4	++	0	Respirations reduced from 60 to 42, cyanosis cleared, pulse improved
94	15 yrs	Lobar Pneumonia	L L L R L L	—	—	4	+++	+	Marked improvement in color and comfort.
95	6 yrs.	Bronchopneumonia	Diffuse Both Lungs	—	—	14	++	0	Marked subjective relief slowing of pulse improved color
96	63 yrs	Cardiac Insufficiency Chronic Myocarditis Arteriosclerosis Acute Bronchitis	Diffuse Process	—	—	3	++	0	Improvement in color and subjective comfort.
97	60 yrs.	Bronchopneumonia Chronic Myocarditis	L L L	—	—	5	+++	+	Marked improvement followed night in tent. Pulse became fuller and stronger

TABLE 2 DATA ON RECOVERED CASES OF PNEUMONIA TREATED IN OXYGEN CHAMBER OR OXYGEN TENT

Case No	Age	Diagnosis	Lobes Involved	Sputum Organism	Blood Culture	Days in Tent	Cyanosis		REMARKS
							Before O2	After O2	
98	40 yrs	Post-operative Bronchopneumonia	R L L.	—	—	1	+	0	Objected to tent No change in condition noted
99	32 yrs	Lobar Pneumonia Mitral Stenosis Edema of Lungs Secondary Anemia	R L L L I L R U L	PN IV	Sterile	0	++	0	Remarkable improvement of patient s color, pulse and edema in 6 hours Hemoglobin 40%
100	50 yrs	Asthma Broncho-pneumonia	L L I	—	—	3	++	0	Diminished cyanosis Was comfortable in tent

A STUDY OF THE DISTRIBUTION OF PHYSICIANS IN THE RURAL DISTRICTS OF NEW YORK STATE

By JOSEPH S LAWRENCE, M D, ALBANY, N Y

IT has been said that adequate medical care is an important phase of the complicated farm problem, that heads of families with small children or elderly people dependent upon them, have hesitated about taking up residence in rural communities where medical care would be difficult to secure or, when procurable, would be too expensive for their limited means Many stories are related of small rural communities disintegrating because the doctor who served them so long and faithfully, died or moved to the city, and no younger man having replaced him, the residents who could possibly do so moved to other localities where medical care was still available Owners of large farms have stated that the lack of a nearby resident physician has caused them difficulty in securing resident farm help Public health workers, probably more than any other group, have emphasized the hardship residents of remote rural districts are obliged to endure because of the difficulty they have in securing competent medical care Complaints that physicians are leaving the rural districts for the cities have only been heard in New York State since the war, or, at least, they have become much more plentiful in the last decade, but they have been so insistent and numerous that the State Department of Health, several medical colleges, and philanthropic organizations, have made serious efforts to stem the tide of moving physicians or to counter it by inducing the recent graduate to begin his practice in the rural districts

For the last three years requests from rural communities for resident physicians, received by the State Department of Health, were transferred to the office of the Executive Officer of the Medical Society of the State of New York, for attention Many of these requests were found to be highly colored with emotion The resident physician who had practiced in a certain community many years, had died, and his loyal patients felt deserted, although, as a matter of observation, in most instances he had been relinquishing his practice in late years to physicians who lived in nearby communities Several young men located in some of these places upon suggestion, only to find, after a few months' residence, that it was economically impossible for them to remain Several such experiences, coupled with the complaint that "We've always had a doctor in our community," indicated the desirability of having some specific knowledge of the distribution of physicians in the state today and, for purposes of comparison, a similar tabulation has been made at ten-year intervals for the last fifty years

With the assistance of the medical directory, the Transactions of the Medical Society of the State of New York, and reports of the Departments of Education and Health, the number and locations of physicians in the state by decades between 1878 and 1928, were tabulated In the entire state the population in these fifty years increased 125%, while the total number of physicians increased 331% Separating up-state from New York City, we find that the population increased 67% up-state, while the physicians increased 194%

Among the 57 counties outside of Greater New York, 24 showed a decrease in population in the rural areas, while only 9 showed a decrease in the number of resident physicians over that of fifty years ago These counties are Allegany, whose population in these fifty years decreased 12% and the physicians 2%, Cayuga—rural population decreased 27%, physicians 12%, Chemung—decrease in rural population[1] 11%, physicians 16%, Chenango—decrease in population 10%, physicians 15%, Cortland—rural population decreased 6%, physicians 53%, Greene—population decreased 11%, physicians 19%, Jefferson—rural population decreased 3%, physicians 11%, Putnam—population decreased 13%, physicians 25%, Schuyler—population decreased 28%, physicians 39%

On the other hand, not a few counties have shown a decrease of population in the rural areas and an increase in the number of physicians Prominent among these are Clinton—population decreased 7%, physicians increased 100%, Columbia—population decreased 7%, physicians increased 44%, Essex—population decreased 7%, physicians increased 40%, Lewis—population decreased 20%, physicians increased 5%, Madison—population decreased 6%, physicians increased 43%, Oswego—population decreased 7%, physicians increased 33%, Otsego—population decreased 7%, physicians increased 59%, Schoharie—population decreased 34%, physicians increased 14%, Seneca—population decreased 12%, physicians increased 16%, Tioga—population decreased 17%, physicians increased 39%, Yates—population decreased 14%, physicians increased 59%

In the following fifteen counties the number of physicians in these fifty years increased 100% or more in the rural areas Albany—153%, Cattaraugus—148%, Chautauqua—141%, Clinton—

[1] Population in Chemung County outside city limits of Elmira. By "rural population" in this paper is meant the population outside the limits of the principal city Of course there is always a suburban population which is more dense than the truly rural and it is likely to have facilities for medical care equal to those of the city and not comparable with the rural districts. This fact must be borne in mind and the proportion of population to physician in the truly rural districts will not, therefore, be as great as indicated in this study

100%, Erie—373%, Franklin—280%, Fulton—100%, Ontario—122%, Orange—213%, Rockland—300%, Saratoga—100%, Suffolk—406%, Sullivan—153%, Tompkins—133%, Warren—262%

It is interesting to note how little change there has been in the ratio of physician to population in the counties where both population and physicians have been decreasing, indicating the probable activity of a common cause

	1878	*1928*
Allegany	1045	944
Cayuga*	1727	1431
Chemung*	1877	2595
Chenango	831	874
Cortland*	850	1932
Greene	908	1005
Jefferson*	1065	1161
Putnam	944	1096
Schuyler	673	799

* Ratio in rural districts. Chemung and Cortland Counties are so small that any part can be reached by physician from the county seat in a half hour

The ratio of population to physician has actually decreased in two of these counties, and in five others there has been but a slight increase In Chemung and Cortland Counties the change has been very marked, but if the size of the county and the extent of good roads are noted, it will be realized that medical care is readily available to any resident of the county

If these figures are correct—and, obviously, they are—how can we justify the many articles that have been written and the concern that has been shown with regard to the vanishing medical care in the rural districts? Aren't there many districts in the state where physicians are actually needed? Aren't they congregating in the cities at the expense of the rural districts? Although physicians are statistically as plentiful in the rural districts today as fifty years ago, there were more in actual number and in proportion to population practicing in the rural districts twenty-five years ago Hence in the memory of the average rural resident, there has been a decrease in the number of resident physicians There are several very convincing reasons as to why this should be so In 1893 there were between 6,000 and 7,000 physicians practicing in New York State In the decade between 1893 and 1903 the Department of Education granted more than 6,000 licenses Since the total number of practitioners was doubled in ten years, a young graduate was glad to take up his residence in any locality where he thought he could develop a practice

Sickness was far more prevalent in the rural districts twenty-five years ago than today The modern methods of prevention and treatment of tuberculosis were only beginning to be appreciated Typhoid fever and associated diseases were common visitants in every community each summer The death rate from diphtheria, scarlet fever and other children's diseases was so high that the infant death rate in this period has been cut in half With disease and sickness so prevalent and means of communication and transportation so inferior, as compared with today, one can readily appreciate how it was absolutely necessary that more physicians should have resided in the rural districts The limitation and prevention of contagious epidemics through our scientific knowledge of bacteria and effective administration of the laws of sanitation, together with the decrease in population, have very markedly reduced the total amount of sickness It is, therefore, very obvious that an economic factor has been operating to make life in the rural districts less attractive to the physician The annual reports of the State Department of Health demonstrate the greater need every community had for a physician in, e g, 1900, as compared with 1928 In that year the population of the state was approximately 7,000,000 and there were reported 130,554 deaths, a rate of 18.3 per 1,000 population More than 30% of these deaths were in infants under five years of age. In 1928, with a population of eleven and one-half million and 151,522 deaths, a rate of 13 0 per 1,000 population, only 3 5% were in the same age group In that early year 13 7% of the deaths were classified as zymotic, while in 1928 less than 3% of the deaths could be placed in this group If for every death of bacterial origin ten persons are seriously ill with the same type of infection, the great reduction of sickness is apparent With both the population and the number and extent of illnesses decreasing, the physicians soon found it difficult to support themselves and their families in the rural districts

Another factor which must be taken into consideration when accounting for the decrease of physicians, is the reduction in the number of irregular practitioners and quacks The elimination of the irregular practitioner has had its effect upon the rural, as well as urban, districts His prevalence a generation ago is indicated by a remark made by Dr Burr, of Binghamton, when discussing a resolution offered by Dr Elisha Harris, of New York, at the annual meeting of the Medical Society of the State of New York in 1878, recommending the creation of a state department of vital statistics Dr Burr remarked "That he should have more faith in such reports if the causes of death mentioned could be relied upon It is well known that more than one-half of the deaths occurred under the treatment of irregular practitioners and, therefore, the value of such statistics is correspondingly reduced" Dr Harris remarked "That this was one of the vexed questions, it is true but, notwithstanding, the duty was being performed in quite a satisfactory manner in at least four or five cities in the

state" (Transactions of the Medical Society of the State of New York, 1878—page 33) The irregular practitioner was not dreaded so much in those days when educational achievements of the best were limited, and in many communities they did a flourishing business

A third factor affecting the residence of physicians in the rural districts is the growth of interest in hospitalization Twenty-five years ago hospitalization was the exception, while today in all severe illnesses, and especially in maternity cases, it is recommended by the physician and sought by the patient. Even in the most pronounced rural districts a growing proportion of maternity cases annually seek hospitalization As a direct result, hospitals have grown more plentiful, almost every city with a population of ten thousand has a hospital The physicians who support the hospital find it definitely to the advantage of the patients and themselves to have their residence in the town where the hospital is located In many instances the physician can do this and still maintain his rural practice The recent graduate whose entire training has centered about the hospital as a medical center, is not willing, when seeking a place to practice, to take up his residence where he cannot have hospital facilities On the other hand, the establishment of a well equipped hospital in a community, encourages the location of physicians and thereby definitely increases the number of physicians to the community Naturally, the physicians, many of whom are specialists, using the hospital, reside near to it, and thus it may be truly said that physicians are, to an extent, congregating in the cities having hospitals

How has the great advancement in communication and transportation in the last fifty years affected the practice of medicine? If John Jones, working on a farm in the summer of 1878, had fallen from a hay wagon and broken his leg, his associates would have carried him to the house and then either taken one of the horses from the wagon or, if fortunate enough to have several horses, they would have saddled another and ridden for the nearest doctor If he lived but five miles away, which would have been a very favorable condition, the messenger would have reached there in about a half hour If by good fortune the doctor was at home, he might have been expected to reach the farm in another three-quarters of an hour Today if such an accident occurred and all other conditions were the same, by the use of the telephone, the automobile and the good roads, the doctor could be expected to reach the patient in one-third the time Generally speaking, the physician with a rural practice can do about three times as much work today as did his predecessor fifty years ago, and with the aid of the telephone, he can be many times more valuable Before the days of the automobile, when sickness abounded, the average physician could not expect to call upon all of his patients daily If he could see them three times a week, he thought he was doing well, and on the other days some member of the family would call at the doctor's house and report upon the progress of the patient Today such service would be considered by the patient and his friends, unreasonable neglect

Good roads and the automobile have not only aided the physician with his patients, but they have made it possible for a large proportion of the ambulatory patients to visit the doctor Physicians in rural districts have very busy office hours daily It is also possible today for rural residents to secure their medical care of city physicians, except in emergency cases, or when the roads are impassable This practice has become so general in some districts that it has seriously affected the annual earnings of the local practitioner and been a powerful factor in influencing him to select a city residence Physicians have found that, occasionally, families who discontinued them as family physicians when living in the country, re-employed them after they had taken up residence in the city

It has been said that the average practitioner of the rural districts is an older man than the average practitioner in the city, but this study has shown that the difference is so slight that it can have no effect upon their relative worth, in fact, the average age of the physicians in the suburbs of some cities is lower than that of the physicians in the city The average period of practice of all of the physicians of the state is 24 3 years, and if the average man is graduated before he is twenty-five years of age, it is obvious that the average practitioner in the state is about fifty years of age Where the community is growing, the average age of the physician is low, due to the fact that the prosperity of the community proves an attraction to the recent graduates and influences them in choosing their location There are nine counties in which the period of practice of the average physician is above thirty years They are Allegany—30 9, Cortland—30 1, Delaware—31 1, Greene—34 4, Orleans—31 0, Otsego—32 5, Schoharie—31 9, Schuyler—30 8, Tioga—34 6 The counties with large cities often have the youngest physicians, as is indicated by the following Nassau—20.2, Monroe—21 3, Erie—21 6, Westchester—21 7, Onondaga—22 4 It would seem, therefore, that there is little ground for the complaint that one frequently hears from the rural districts that their physicians are not up to date, that they were educated too long ago to be familiar with modern medicine

But aren't there sections in New York State where adequate medical care is actually wanting? It is altogether possible that there are The death of an active physician in a rural district is a serious loss, but we have never known a vacancy

of that kind to exist very long, as a matter of observation, usually the location is filled within a few weeks If, however, the physician was not very active and his territory was being covered by neighboring physicians, another man may not locate there unless the neighboring physicians have greater territory than they feel they can cover adequately In this office we file the vacancies as they are reported to us and, likewise, have a list of physicians who are looking for locations, and frequently we have been of service as a clearing house There are, however, many communities where actual medical care is not wanting, but where the citizens are not fully satisfied with existing conditions

Unlimited distribution of health information, both by official and unofficial agencies has given the general public a greater knowledge of the newer ideas of medicine and sanitation, and awakened in it a great desire to keep well and avoid illness Publicity on health subjects has, since the war, become very popular, not only with professional and semi-professional publications, but even the newspapers and the most conservative magazines have engaged in discussions of problems in public health and sanitation. A generation ago the principal source of information on matters of health, to the average rural resident, was advertising matter distributed by the patent medicine vendor, and each household had its shelf of patent medicines These were purchased from the druggist without advice or consultation with the physician Correct information issued by responsible agencies has gradually diminished the size of these shelves and proportionately increased in the minds of the people a demand for reliable medical care and advice The young mother of today is not content to bring up her child on grandmother's remedies, but she must call a physician when he is ill The public has lost much of its faith in tonics and panaceas, and accordingly it keenly feels a need of the support of a nearby physician

The aim of every official public health agency is to make residence in the rural sections as healthful and sanitary as in the large city The rural public appreciates this and feels that for its accomplishment physicians should be as plentiful in the rural districts as they are in the cities This idea is deeply entrenched in their minds, in spite of the fact that, except in emergency, they will seek most of their medical advice from the physicians residing in the city

What should be the ideal ratio of physicians to population is an interesting question and one which we shall not attempt to answer in this paper The average in the State of New York is one physician to 649 people, in New York City it is one physician to 549 people, and in the 57 counties outside of Greater New York, it is one physician to 812 people The highest county ratio is in Lewis County, with no hospital, where there is one physician to 1,321 people, and Warren County, with a splendid hospital, has the lowest ratio—one physician to 603 people.

But this ratio does not tell the whole story The rural practitioner is almost without exception a general practitioner and will respond to any call, while a certain proportion of the city physicians are specialists and available only for their particular specialty, as, for instance, in the City of Albany there are 233 physicians, giving the city a ratio of one physician to 516 people If the 95 who limit their practice are deducted, we shall have but 138 left as general practitioners and the ratio then becomes one physician to 872 people, a ratio that is as high as that found in some rural counties Of course, in some instances the services of a general practitioner are not so necessary, the symptoms pointing unmistakably to the field of the specialist The sophisticated public prefers to make its own diagnosis and selection of specialist. This practice is one of the factors which is aiding to increase the number of specialists, who are no longer limited in residence to the largest cities, but will be found in every hospital community The specialist, therefore, should not be reckoned the equal of the general practitioner when computing a ratio, but it would hardly be fair to eliminate him completely

As the idea develops both in the mind of the public and the physician, that the greatest service he can render is to keep his clients from becoming patients, demand for his advice will greatly increase Proof of this statement has been frequently noted in areas where intensive health educational campaigns have been conducted If it were simply a matter of taking care of the seriously ill, we might have sufficient physicians now, but when we consider the needs of preventive medicine as it is developing, we realize that there will be need for many more as the practice becomes more general

In conclusion, therefore, it may be said that mathematically the State of New York is better supplied with physicians today than it has been at any time in the last fifty years, but the actual number of physicians in the rural districts is not so great today as it was twenty-five years ago However, the addition of the telephone and automobile to the physician's armamentarium has more than offset the decrease in number so far as rendering service to the population is concerned On the other hand, the intensive public health educational campaigns have stimulated in the public greater interest in health, which manifests itself in the greater concern individuals take for the preservation of their health, which, naturally, calls for increased demand upon physicians for advice. There are many places in New York State where active young men can build up lucrative practices, particularly if they feature preventive medicine programs

INVERTED LANDRY'S PARALYSIS*

By EUGENE N BOUDREAU, M D, SYRACUSE, N Y

IT is perhaps unjustifiable to attempt reporting a case on which there are no confirmatory pathological findings For this I can only ask you to bear with me There are, however, it seems to me, certain aspects of this case which will justify its discussion both from clinical and morphological viewpoints

Before reciting the case history and clinical findings let me point out two salient points in it which stand out strikingly First there is a descending paralysis—beginning with the brain stem and passing down structures of the neuraxis to cord levels Secondly this demonstration raises the question as to whether our present conception of the innervation of certain structures is correct. I refer to the muscle which purses the lips or closes the mouth, i e. the orbicularis oris It is commonly believed these muscles derive their nervous impulses from the facial nerve I believe from the evidences in the case I shall here report that we have further evidence to support another view This is that the hypoglossal nucleus sends fibers to the 7th and thence to these muscles

Now let us briefly review the Landry conception In the years since Landry circumscribed the syndrome, which bears his name much discussion has arisen as to just what should be its limitations Some argue for the exclusion of many types of cases that are not strictly conformatory to his conception Others argue that with greater knowledge and more refined microscopical technique many cases that are not strictly conformatory nevertheless belong there, in other words, these latter believe the syndrome of Landry should be more inclusive But this seems to me to be a somewhat useless contention either way Definition only serves an academic purpose. A sharp differentiation seems impractical

Landry's original conception as drawn in his report was "An acute paralysis ascending from the legs to the arms, and soon involving the bulbar muscles The paralysis was unaccompanied by marked loss of sensation nor did it involve the sphincters The paralyzed muscles retained their farradic excitability, the intellectual faculties remained unimpaired and fever was not prominent" Furthermore, after death no lesions were found in the nervous system to explain the rapidly fatal symptoms Although the nerves were not examined, the results of careful microscopic examination of the spinal cord by several observers were absolutely negative

Then in 1896 in a characteristically thorough fashion Pearce Baily and James Ewing surveyed the forty-two cases in the literature up to that date and reported their conclusions in the New York Medical Journal for July of that year as follows In order to clarify the conception of this syndrome, they grouped the cases which they, after investigation, concluded acceptable for their study to the original description of Landry's into four classes or groups

1 Cases in which no histological changes were demonstrated in the nervous system
2. Cases in which there was an acute exudative inflammation of the cord and medulla and sometimes of the brain
3 Cases in which there was an acute inflammation of the peripheral nerves
4 Cases in which there was acute inflammation of both central and peripheral nervous system

Their conclusions were summarized as follows

1 Acute ascending paralysis is an acute toxemia in which the poisonous agents affect chiefly the nervous system
2 The most common seat of the lesion is in the spinal cord and in the medulla, and it may be present in the cortex and in the nerve roots When in the spinal cord the lesion is that of acute anterior poliomyelitis, namely, an acute exudative inflammation following the distribution of the central branches of the anterior spinal artery with infiltration of the circumvascular sheaths, degeneration of the ganglion cells, loss of structural elements and with or without degeneration of anterior roots The lesions in other parts of the cerebral spinal axis are of similar nature
3 The evidence that the lesion of typical Landry's paralysis may exist in the peripheral nerves alone is based on a single case reported twenty years ago by Dejerine When the lesion affects the peripheral nerve, there are increases of neuroglia cells and degeneration of nerve fibers
4 It is at present impossible to deny that occasionally ascending paralysis may run a fatal course without leaving demonstrable histological changes in the nervous system It is certain that the case with negative pathology report did not present the marked vascular lesions of acute anterior polio, but it seems probably there were changes in the ganglion cells demonstrable by delicate methods

* Read at the Annual Meeting of the Medical Society of the State of New York, at Albany N Y May 23 1928

From the present data it seems to us impossible to distinguish by clinical symptoms the different types of lesions

Since then there has been further literature, but it does not clarify the situation measurably, so I will not burden you However, it should be mentioned here that other cases of descending paralysis, remarkably few however, have been reported

Case report

Mr W D, aged forty-one was referred to me by Dr Edwin Shepard of Syracuse He was a builder and contractor A review of his personal history revealed that he had had a healthy boyhood While in the Klondyke in 1905 he was ill about seven weeks with typhoid He had had a left middle ear disease for twenty years, the ear frequently discharged He had had an operation for appendicitis twenty years previously and hernia three years previously He had had pneumona February 1926 He never had had convulsions of any kind He had never been injured Married at 26 Has five healthy children living, none dead, no miscarriages He had always done heavy work and pushed himself hard

About August 15, 1926 he had three or four days of illness, suffering from malaise and abdominal discomfort By August 27th he first noted he could not hold a cigar firmly in the left corner of his mouth and the lips on that side were a little numb About ten days later he first began to have trouble moving food around in his mouth There was also then some numbness of the left upper and lower lips Weakness of the left face was apparent, saliva drooled from the corner of his mouth He suffered at times with headache, and also ache in the back of the neck There had never been nausea or vomiting

All of the symptoms had subsided in the two weeks just previous to September 18 On September 13, Doctor Shepard found the pulse rate 60, blood pressure 128/88, weight 182 pounds, temperature 98 4 Left side of tongue somewhat numb

Neurological examination September 18 Pupils equal, regular, reacted to light and convergence Fundi normal Cranial nerves I to IV normal V—a little hypasthesia at left corner of nose and at left corner of mouth on lower lip VI—normal VII—slight peripheral (?) weakness of left, could not whistle (See illustrations) VIII—middle ear deafness left side IX, X, and XI—normal XII—weakness of tongue, protrusion impossible, atrophy present Speech consequently difficult and thick Inability to purse lips Deep reflexes lively and equal Superficial reflexes lively, equal No Babinski phenomena, no clonus Sensation normal No incoordination Blood Wassermann negative Cerebral spinal fluid Wasserman negative, seven cells, negative globelin

There had been an epidemic of poliomyelitis in August that year It was considered the man had had a mild bulbar polio Later, however, further symptoms occurred By October 15, he began to have difficulty in swallowing, and a little later there appeared fibrillary twitching of the right deltoid and in other muscles of the upper arm Symptoms progressed slowly By January 12, when he was seen by Doctor Casamajor he was unable to swallow anything but liquids His speech was nearly unintelligible Palate motionless He was becoming emaciated, his right arm was weak, mainly in the upper arm, but it was difficult to grasp a pencil for writing

The condition progressed until he could not talk Saliva distressed him, for he could barely swallow He ate little, grew weaker, and died suddenly March 2, 1927 His mental faculties were unaffected to the last.

In brief then there was involvement centered about the XIIth nucleus, but the process later involved the IXth and Xth, then the cervical segments of the right side Possibly left VIIth and Vth (descending or spinal portion) were first involved No lower portions were involved, probably because death interrupted

Conclusions

1 This case clinically fulfills the essential conditions of a Landry's syndrome, (i e, progressive paralysis, no sensory or inconspicuous sensory symptoms, little or no temperature, no mental affection) but inverted in sequence

2 It lends strong support to the belief that the orbicularis oris receives its innervation from the hypoglossal nuclei

A CONSIDERATION OF THE MECHANICAL FACTORS IN HAIR GROWTH*

By HERMAN SHARLIT, M D, NEW YORK, N Y

A rather recent experimental study detailed below supplies a good text for a discussion of the mechanical factors involved in the hair growth process And therefrom, follow certain therapeutic considerations that should be of interest to the dermatologist

The hair grows from a relatively fixed point, lifting the products of its growth by continually throwing building stones about the base of the lengthening structure The procedure is very much after the fashion of building a smoke stack by each time lifting the cylinder to place another row of bricks under it Abiding by this analogy for the moment, if a single group of men working at this task, renewing their energy after the manner and at the rate characteristic of the species were to labor at so building the stack, each succeeding row of bricks would be laid at the expense of a greater portion of the total available energy of the group This would result in a constantly decreasing rate of production which rate would approach zero as the whole of renewed energy of the group is called upon to lift the stack to lay that last row of bricks In short, the height to which the stack arose and the rate of its rising would be a measure of a biological phenomenon—in this case, the foot-pounds of energy available in a given group of men and the rate of its renewal

For the hair, the hair papilla and the adjacent portions of proliferative follicular cells elaborate the vital forces determining the rate and limits of hair building The vital activity about the base of the follicle must not alone overcome the increasing load measured by the weight of the superimposed hair, but has, too, to meet the friction forces set up in the upper third of the follicle where a free hair shaft is working its way through a snugly fitting channel

In the October, 1926, issue of the American Journal of Physiology appeared a paper by Seymour entitled "The Effect of Cutting Upon the Rate of Hair Growth" This report of an experimental study deserves careful consideration not alone because the data were collected after the manner required of acceptable experimental evidence, but particularly since it is the only experiment carried on through a long enough series of observations to justify the attempt at an interpretation of their meaning Seymour collected "shavings" from the zygomatic areas of the face of one individual during the spring and summer months of two years These "shavings" cut each time by a new safety razor blade, after growth periods of from 12 to 50 hours, were cleaned, dried and an adequate number of samples subjected to micrometric measurements of their lengths Below follows Table 1 indicating his findings

The data show clearly that as the growth periods proceed from less than 16 hours, to 50 hours and longer, the rate of growth diminishes, thus, the average growth per hour for the growth periods of less than 16 hours in series 1 and 2 are respectively 151 per cent and 148 per cent of those of the 41 to 50 hour periods of growth Seymour concludes from his data that "It seems obvious that the mere severance of the hair shaft materially modifies the growth process Whether this cutting serves as a stimulus directly or indirectly by removing an inhibition can only be conjectured and the present study offers no suggestion as to the mechanism by which the growth process is modified" As we see it, we are presented with two alternatives in interpreting these data, a direct stimulation of the growth process by the mechanism of shaving or an indirect enhancement of it by way of the removal of resistance Seymour put the first of these alternatives to the test—that of the increased rate as due to a stimulation resulting from the hyperemia accompanying the process of shaving Of this Seymour says

TABLE I

Showing Growth Rates at Various Periods

Hours of Growth	Average Hours		Total Growth		Average Growth Per Hour	
	Series 1	Series 2	Series 1	Series 2	Series 1	Series 2
			mm	mm.	mm.	mm.

From Seymour R. J 'Effect of Cutting on Rate of Hair Growth. *American Journal of Physiology* LXXVIII 281 (1926)

Read at the Annual Meeting of the Medical Society of the State of New York, at Albany N Y May 22 1928

"However repeated observations failed to give any support to such an explanation Frequently but one side of the face was shaved while the beard on the opposite side was left uncut, but subjected to the same conditions, other than the actual cutting, as the shaved side, to both sides of the face hot water was applied, the usual soap lather was "rubbed in" by massage, and in every other way right and left sides were treated alike, except that one side was left uncut until the next shaving period However, this uncut side was mechanically irritated by use of a razor blade so dulled that actual cutting of hair did not occur"

We believe that the conclusion is forced upon us, one that strangely enough Seymour fails to consider—that shaving in removing a "load" upon the hair follicle increased rate production Our opening paragraph is explanatory of the physiological mechanism underlying this conclusion Before this mechanistic hypothesis may be accepted as interpretative of Seymour's data several other aspects of the mechanics of hair growth as applicable to his data must be evaluated In the first place, our argument that the hair length meant resistance load to the growth process involved the assumption that the lengths measured were indices of the weights This assumption is correct if the hair through out its length has a constant diameter For the short hair lengths dealt with in these data (longest less than 1 mm) a constant diameter is a reasonable assumption Then, too, for such short hairs the influence, for example, of the tug of gravity, or the added weight from attached foreign particles are reducible to a nullity Of course, as hairs grow to lengths permitting them to incline over and take support on the surface of the skin most of the weights of hairs no longer act as a resistance load operative against growth We mention these features as insinuating themselves into a mechanistic argument to point out that the nature of Seymour's data precludes the operation of these particular factors, and, as well, to indicate that in all probability experiments such as Seymour's on hairs of substantial lengths would so far mask the small influence of weight resistance load that its operation would be considered negligible

We submit, then, that the weight resistance load is an operative principle in the physiology of hair growth though of slight significance in the practical aspects of this growth However, the principle of resistance load assumes a role of importance in the second feature of its application to hair growth Just above the opening of the duct of the sebaceous gland into the hair follicle, the hair shaft is free seeking the skin surface through the channel of the upper one-third of the follicle Where one body is sliding forward on another as the hair shaft on the walls of the distal one-third of the follicle a resistance to this sliding movement is engendered In mechanics it is spoken of as friction resistance We may here insert our final reference to Seymour's experimental data to complete the mechanistic arguments as applicable to his experiment The attempt was made by the use of a new blade for each shaving to cut the hair as close to the skin surface as possible, this served, insofar as the operation was successful to keep the lengths of the intra-follicular hair shafts constant. This would serve to give a constant value to the weight and friction load resistances represented by the intra-follicular hair shafts In which case, the shavings would represent the only "load" variables and the measure of these variables sufficient data with which to defend the thesis herein upheld

We need not concern ourselves with the physical laws applicable to friction forces—the influence of motion rate, of surface areas, etc , for in them we will find nothing reasonably pertinent to our discussion However, the lubrication of surfaces subjected to friction forces is an important factor in the reduction of friction resistance, and, in the hair follicle we meet through the agency of the sebaceous gland an oiler for the adjacent surfaces of hair shaft and follicular walls Smoothness of surface, too, modifies the friction resistance between sliding surfaces, and while the hair shaft has a surface of fairly constant smoothness the follicular walls made up as they are of the epidermal layers of the cutis are subject to those proliferative and degenerative changes that all too frequently attack these layers which changes make for marked differences in surface evenness

The products of sebaceous gland activity and the state of health of the epithelial surface of the skin may as we suggest enter as mechanical factors operative on hair growth The dermatologic clinic supplies the evidence of the effectiveness of these structures in dysfunction to induce alopecia Seborrhea is accepted as the chief offender in the production of alopecia It is considered primarily a disease of the sebaceous gland perverting the chemistry of its glandular activity in a manner yet unknown Whatever the nature of the perversion, the effect is generally one of giving either a greasy, dry, crusted, or scaly scalp alone or in compatible combinations

The invaginated portions of the epidermis forming the walls of the distal one-third of the hair follicle suffer the same changes as is presented by the scalp surface in seborrhea—all calculated probably to heighten the friction resistance to the outwood propulsion of the hair shaft In practice, at least, a majority of

the patients seeking relief from sebarrhea are most concerned about the accompanying loss of hair Our therapy in seborrhea is as various as it is ineffectual One cannot, in fairness, say much more for our efforts in staying the progress of the alopecia

We are indeed aware of the supreme importance of the vital energy about the growing base of the hair root, an energy capable on occasion of forcing hair shafts through aberrant pathways of maximum resistances, per example, ingrowing hairs While in our discussions and our attempts at therapy as well, we are given to speak of stimulating hair growth, that is to say, speeding up the vital force behind growth we perhaps overlook the somewhat significant fact that we know well nigh nothing of the physiological factors underlying this vital energy—at least nothing that can be translated into successfully applied rational therapeusis We abide by constitutional and hereditary deficiency in this vital force as the expression of a lost cause We administer endocrine substances or their extractives in childlike hope and apply local remedies that, while they serve best, can not to the least thinking be considered stimulating to that vital energy

We hazzard the suggestion that our therapy in alopecia symptomatica is of greatest aid in increasing hair growth in the degree to which it removes by cleansing the scalp, the simple resistance factors to hair propulsion It is a fact that baldness is far more prevalent in man than in woman While unwilling and unable to dispute the evidence presented by Dorothy Osborn[1] to the purpose that baldness may be hereditary and a dominant trait in male and recessive in the female, we may be permitted to call attention to the fact that persistent care of the hair and scalp, frequent massage and manipulation of the scalp to keep its surface clean and the follicular openings free of inspissated sebum and epithelial debris is a trait distinctly dominant in the female and recessive in the male In the last decade with bobbed hair in vogue there has been in our experience an increasing number of women complaining of alopecia symptomatica Can it be that with a shortening of the hair there has been a relaxation in feminine zeal for meticulous care of the scalp?

Seymour's careful experiment outlined above and interpretable, we believe, in purely mechanical terms is, in our present knowledge of the physiology of hair growth, an excellent guide to therapy. If we can not whip up that vital energy that elaborates hair cells we may at least seek to remove the elements that hamper the full play of these forces Scalp lotions containing keratolytic agents and fat solvents reinforced possibly by a rubefacient, this plus mechanical rubbing of the scalp is a sensible procedure In truth, it is usually all we do for a patient, though we speak of stimulation to growth And may it not be true, that beauty salons and barber shops ultimately get most of our patients because they specialize in applying these principles of scalp hygiene that makes for the removal of the mechanical interference with the best efforts of each individual's constitutional vigor for hair production

HOW ARE HOSPITAL APPOINTMENTS DISTRIBUTED?

A Study of the Situation in New York State

By MICHAEL M DAVIS, Ph D, CHICAGO, ILL

THE value of sufficient hospital service for the community is hardly second in importance to the need of hospital connection for the physician. What proportion of the medical profession have the privilege of practicing medicine or surgery within a hospital? What proportion have no such privileges? Is the privilege or its denial connected with the age, specialty and training of the physician? Is it merely a matter of location and physical accessibility to hospitals?

The American Medical Association has furnished certain information on this subject for the country as a whole, but for New York State more intimate and in some ways more reliable data are available from the State Medical Directory The hospital appointment of each physician is listed here as annually furnished the Society by the physician himself In connection with a study of the relation of hospitals to medical practice, undertaken in the course of a series of

*The aid of Dr Helen C. Coombs in the statistical work is gratefully acknowledged.

hospital studies made by the writer on a grant from the Rockefeller Foundation, the facts available in the Directory have been analyzed* for the purpose of answering so far as possible the questions raised in the preceding paragraph The 1927 State Medical Directory showed 17,091 physicians in New York State, excluding those who are said to have retired from practice Of these 8,964, or fifty-two per cent, state that they hold some hospital appointment

What Is a Hospital Appointment?

The reliability of these data must be weighed Many physicians may not report all their hospital appointments On the other hand, it is unlikely that a physician who fills out his card for the Society at all, would not specify at least one hospital appointment if he had any But what is a "hospital appointment?" An "appointment" may imply a position as chief of an important service, involving large responsibility, or may mean a very minor or subordinate post It may mean a full-time appointment in a large laboratory, or a resident or administrative position It may be only a place on a so-called courtesy staff giving the physician the privilege of treating private cases in the hospitals with perhaps further limitation to medical and obstetrical cases only The term "hospital appointment," therefore, actually covers a wide range of hospital privileges Hence the available statistics tell us something rather significant about those physicians who report no hospital appointments of any kind, but the statistics do not permit a detailed analysis of just what is meant by the appointments which are reported

General Practitioners versus Specialists

We learn something when the physicians are classified according to whether they are general practitioners or specialists Only those physicians are recorded as "specialists" who reported to the American Medical Association that they were confining their practice to a specialty Three thousand one hundred sixteen physicians thus record themselves, this being 18 per cent of all the physicians in the state, leaving 13,975 or 82 per cent who are in general practice. The remarkable fact then appears that of the specialists, 3,089 or 99 per cent have hospital appointments, while of the general practitioners, this is the case with only 5,535 or 40 per cent These facts are brought out in the accompanying chart. Like many other statistical facts, this difference between the general practitioners and the specialists raises more questions as to whys and wherefores than the facts can answer But the contrast itself is challenging enough

Table I works out the figures in more detail showing the distribution of all physicians in New York State as to hospital appointments, classified into groups according to size and type of community For the purpose of comparing conditions in different communities, an analysis was made of twenty-six counties, none of which contained any town of over 15,000 population. Only four of these have any town of over 10,000 Six of these counties had no hospitals within their borders, although some portions of them are served by hospitals in neighboring counties These are the only six counties in the state having no hospitals These twenty-six counties are arbitrarily designated in the table as "rural areas" Twenty cities of from 10,000 to 100,000 population are taken as another group, the six cities of between 100,000 and a million population as still another, and finally, New York City

In some cities the presence of a state hospital for the insane brings to the locality a number of specialists, vitiating comparisons with other communities Hence the psychiatrists connected

TABLE I

DISTRIBUTION OF ALL PHYSICIANS IN NEW YORK STATE, ACCORDING TO LOCATION, TYPE OF PRACTICE, AND HOSPITAL CONNECTIONS

	Groups	All Physicians			General Practitioners			Specialists		
		Total	Hospital[1] Number	Appts %	Total	Hospital Number	Appts %	Total	Hospital Number	Appts %
1	6 counties without hospitals	139	18	13	139	18	13			
2	20 counties with no town larger than 15,000	724	199	28	658	134	20	66	65	99
3	Remaining counties (31) excluding all cities given below	1991	710	35	1749	473	27	242	237	98
4	Twenty cities, 10,000-100,000	976	569	58	731	324	44	245	245	100
5	Six cities over 100,000	2189	1154	53	1721	689	40	468	465	99
6	Greater New York	10877	5779	53	8977	3897	43	1900	1882	99
7	State Psychiatrists in above cities	195	195	100				195	195	100
	Total	17091	8624	50	13975	5535	40	3116	3089	99

with state hospitals in any of the cities or counties tabulated have been deducted from those cities and are shown separately

Large Communities versus Small

It will be seen that in the six counties without hospitals there are no specialists, and that only 13 per cent of the 139 physicians in these counties report any hospital appointments These appointments are, of course, in hospitals in neighboring counties The twenty other rural communities show that only 20 per cent of the general practitioners have hospital appointments as compared with 40 to 45 per cent in the cities The remaining 31 counties in New York State, excluding the cities tabulated, are largely rural in nature, although they include some towns of fair size and show 27 per cent of the general practitioners with appointments in hospitals

To sum up three-fourths to four-fifths of the general practitioners in rural areas have no hospital appointments, and slightly more than half of the general practitioners in urban areas are in the same position.

The percentage of specialists in the different communities varies widely In the twenty rural counties having hospitals, there are 9 per cent of specialists, in the twenty smaller cities the specialists include 26 per cent, in the large cities, 21 per cent, and in New York City, 17½ per cent

A detailed table (not printed here) has been prepared, showing each county and city individually and indicating that in nearly all of the cities and even in the counties outside of the cities, almost every one of the specialists is connected with a hospital Practically speaking, it may be said that all physicians who confine their practice to a specialty have hospital connections

These facts lead to the very important point that the question of the availability of hospital facilities for physicians turns upon the general practitioner Studies of other states should be made to see how far this holds generally

Age of Physicians in Different Communities

How much are hospital privileges influenced by age? Do the younger or the older men have the better chance?

The physicians in the five selected groups of communities in the state were tabulated according to the date of graduation from medical school, this being taken instead of age in years The proportion of physicians who graduated before 1900 (mostly men from 55 to 60 years of age, or over) is very large in the rural areas and diminishes progressively as the size of the community, whereas the proportion of young men changes in just the reverse direction In percentages, the physicians graduating before 1900 constitute 68 per cent of the profession in the rural counties without hospitals, 58 per cent in the twenty other rural counties, 42 per cent in the small cities, 33 per cent in the six large cities and down to 28 per cent in New York City On the other hand the men graduating from 1911 to 1922 are only 14 per cent of the profession in the rural counties without hospitals and 20 per cent in the other rural counties, whereas they constitute 33 per cent in the small cities, 42 per cent in the large cities and 48 per cent in New York City As to the middle group, who graduated between 1901 and 1910, their proportion is remarkably constant, nearly 25 per cent for all size groups except in the rural counties without hospitals, where it is only 18 per cent. The young graduates of less than five years' standing (1923-1927) number 5 to 7 per cent in the rural areas and towns, and about double that percentage in larger places The physicians have also been classified in age groups according to whether they are specialists or general practitioners The specialists, as would be expected, are much less numerous in the oldest and the youngest age groups and much more numerous in the two middle groups

Hospital Appointments and Age of Physicians

The further fact then comes out, that the frequency of hospital appointments among physicians varies markedly with age. The specialists are not included in these comparisons, since practically all have hospital appointments If we take all the physicians in general practice together, we find that of the 3,819 physicians graduating before 1900, only 26½ per cent have hospital connections Of those in the 1901-1910 group, 42½ per cent have a hospital connection, while of those graduating between 1911 and 1922, the percentage rises to fifty-seven. Among the young men graduating since 1923 hospital appointments are naturally fewer, being 37 per cent, but this is still much higher than among the oldest group These differences hold in the rural counties as well as in the two groups of cities and in all the boroughs of Greater New York Generally speaking, it may be stated that hospital appointments are more than twice as frequent among the physicians graduating between 1911-1922 (men between 35 and 45 years of age) as compared with the physicians who left medical school before 1900

These figures may be looked at in another way Of the general practitioners with hospital appointments, only 19 per cent are in the oldest group, 22 per cent in the 1901-1919 group, 45 per cent in the period 1911-1922 and 14 per cent in the youngest group Nearly 59 per cent of the general practitioners *with* hospital appointments graduated in 1911 or thereafter, whereas among the general practitioners *without* hospital appointments 58 per cent graduated before that year

Medical School and Hospital Appointments

The medical schools from which the physicians graduated were also classified in relation to hospital appointments, using the grades adopted by the Council of Medical Education of the American Medical Association This classification has been applied only to the 5,815 doctors in general practice who graduated since 1910, as the changes in medical schools render the inclusion of men of previous periods unjustifiable

In the six rural counties without hospitals the number of physicians is too small to use the figures In the twenty other rural counties, 33 per cent of the 1911-1922 graduates of Class A schools have hospital appointments, while the percentage of appointments among the men graduating from B, C, defunct or foreign schools is actually a little higher—36 per cent The number of physicians in the latter group is, however, only eleven, too small to make the percentage very reliable

In the cities the figures are large enough to make more trustworthy comparisons They show a much greater frequency of hospital appointments among the Class A graduates In New York City, 62 per cent of Class A graduates of the 1911-1922 period have hospital appointments, as contrasted with only 38 per cent of the graduates from the other schools In the six other cities of over 100,000 population, hospital appointments among the Class A men are 53½ per cent, and only 42½ per cent among the graduates of other schools In the twenty small cities, Class A graduates also show 53½ per cent of hospital appointments as compared with 46½ per cent among the graduates of other schools

One may draw the conclusion that in the larger cities, the Class A graduates of 1911-1922 have a much better chance at hospital appointments than the graduates of inferior, defunct or foreign schools In the small towns and rural areas the graduates of inferior schools have relatively better chance for hospital appointments than the same men would in the cities

What Determines a Hospital Staff Appointment?

Whether or not a physician secures a hospital position obviously depends upon several factors One element is the presence of hospitals in his community or its vicinity A tabulation was made of the number of *hospital beds per physician* in the communities which were specially studied, and there is some indication that this is a more or less significant index of the frequency of hospital appointments But a larger number of places and other states must be studied to decide whether or not this figure would be useful as such an index

The form of hospital organization also affects the proportion of the profession having appointments These are communities in which the hospitals are proprietary, owned or managed by one or a few physicians, and closely limiting their privileges to a small number of the local profession There are also non-proprietary hospitals, particularly in the larger cities, which have relatively small closed staffs

Given a certain number of institutions and beds in a locality, together with the prevalent types of hospital organization, how far do the standing and qualifications of physicians affect the likelihood of their receiving hospital appointments? Local factors of a personal character enter as well as more general considerations For all these reasons, statistics of the kind presented in this article must be interpreted with caution, but the indications are that in New York State, the appointment of physicians to hospital privileges is affected to a degree by professional standing and qualifications, and that the physicians with hospital appointments represent, by and large, the pick of the profession

Summary

The following conclusions appear to be trustworthy so far as New York State is concerned

1 In both rural and urban communities the younger general practitioners have a much better chance for hospital appointments than the older men, in the cities, the contrast in favor of the younger man is very marked The graduates of the period 1911-1922 show the maximum proportion of appointments

2 Graduates from Class A schools of the period 1911-1922 have, in the larger cities, a much higher proportion of hospital appointments than physicians who graduated from other schools during the same period

The trends of medical practice and the relations of physicians to hospitals are matters of paramount significance to the profession and of no little interest to the general public The conclusions reached for New York should be confirmed, limited, or developed by similar analyses of facts from other states The comprehensive and growing body of information collected by the American Medical Association furnishes important initial data and it is to be hoped that further studies will be undertaken by the Council on Medical Education and Hospitals

THE EYE IN DIABETES*

By WILLIAM T DAVIS, M D., WASHINGTON, D C

HIRSHBERG'S classification in 1900 of the retinal lesions is as follows

(1) Central punctate retinitis There are seen small, brilliantly white spots in the vicinity of the macular These spots may coalesce forming larger masses at the macular or they may mass above and below the macular, resembling retinitis circinata The stellate arrangement seen in hypertensive retinitis does not occur Confluence of these small white spots may occur throughout the retina forming large white areas Friedenwald[1] thinks that this form of retinitis when present without nephritis may be considered diabetic retinitis, it may, however, be present without diabetes It sometimes precedes the glycosuria No doubt this is true since we are now entirely familiar with the form of diabetes that runs a higher than normal blood sugar over a long period of time so that the patient has the disease some time before there is glycosuria

The significance of retinal changes in diabetes is probably one of vascular disease and means diabetes of long standing, as in the cardo-vascular-renal retinal changes seen in that profound metabolic disturbance known to us as Bright's disease. Holloway thinks that punctate retinitis is seen much more frequently in diabetes than in arteriosclerosis

Altnow[2] thinks hypertension may play an important part in the diabetes of elderly persons Instead of terminating in cerebral arteriosclerosis or chronic nephritis it may terminate in pancreatic vascular sclerosis, diabetes resulting The following retinal appearances suggest diabetes according to this author

(a) The retina is redder than normal
(b) Punctate retinal hemorrhages
(c) The grayish white spots at the macular already described
(d) Fan formation at the macular
(e) Retinal arteriosclerosis
(f) Chorioidal sclerosis

De Schweinitz[10] says "Central punctate retinitis is the form most suggestive of diabetes" In addition to this punctate form we see exudative retinitis characterized by widespread, yellowish white areas, probably due to the coalescence of the small spots, the lesions being arranged above and below the macular or massed in the central retinal area Smaller white exudations are scattered elsewhere in the retina

(2) Retinitis hemorrhagica diabetica with resulting proliferative, inflammatory and degenerative changes

(3) A rarer pigmentary retinitis which we now think is probably retinitis pigmentosa associated with diabetes

The existence of true diabetic retinitis remains to be proven The mingling of lesions depending on vascular hypertension, arteriosclerosis and nephritis on one hand and hyperglycemia on the other have disappointed every attempt thus far to demonstrate just what role is played by diabetes per se

Doyne[3] mentions diabetes innocens where large amounts of sugar are excreted without detriment, uninfluenced by diet and occurring mostly in the young There is also the acute diabetic of early life who dies early, and the mild diabetic of middle age who lives for years and in whom there is glycosuria only after carbohydrate indiscretion The last named cases are the ones to develop retinitis Some are due to pancreatic disease and some to endocrine disturbance, but arterial hypertension and vascular disease are the leading factors in producing the retinitis

The characteristic hemorrhages are round, very small ones not easily seen and occurring in the deep layers of the retina I have not seen these hemorrhages in any but diabetics They may be the earliest lesion in the retina. Larger hemorrhages may occur together with exudates and with the vascular degeneration may resemble hypertensive retinitis As before mentioned the macular star is unusual The retinitis associated with diabetes being a late manifestation and not occurring in juvenile subjects is a strong argument that it is due to the vascular disease and not the diabetes The prognosis for life in so called diabetic retinitis is not so grave as in the renal or hypertensive retinitis Nevertheless, I believe it is of ill omen as it signifies vascular degeneration It does not occur until disease of the vessels takes place. Hence insulin cannot be expected to relieve it It is analogous to the vascular changes occurring in nephritis or vascular syphilis Though the disease may be arrested the damage has occurred and cannot be repaired

To determine if the retinitis be due to the hyperglycemia or other toxic agents in the blood of diabetics, or to the vascular changes induced by this disease, a careful study must be made of the blood pressure, blood chemistry including blood sugar, non-protein and urea nitrogen and blood fat and the renal function

The small punctate hemorrhages are probably due to characteristic changes in the vessels This histopathology remains for an interesting study and may assist us in knowing more of the early changes in diabetes

Wilder and Wagener[4] conclude that the primary cause of the retinitis associated with diabetes is in accompanying pathologic changes in the vascular system, the metabolic disturbances playing at most a secondary part. After discussing a series of cases their conclusions are "We

*Read at the Annual Meeting of the Medical Society of the State of New York, at Albany, N Y May 23 1928.

believe, therefore, that the retinitis of diabetes is the retinitis of cardio-vascular-renal disease modified and in appearance and in stage of occurrence by the metabolic disturbance associated with diabetes In cardio-vascular-renal disease there are degrees of renal involvement which indicate the stage of the vascular and of the renal process In a similar manner the various types of diabetic retinitis mark the degree of vascular and of renal pathology complicating the diabetes"

Renal retinitis may occur in those with diabetes just as in those without it In the acute diabetes gravis, retinal lesions are rarely seen Bardsley mentions two cases of diabetic retinitis in persons 26 and 35 years of age respectively

May not the tendency toward retinal hemorrhages and the resulting proliferative changes find its explanation in a sclerosis of the finer retinal vessels with hyaline transformations of their walls induced by the hyperglycemia? Little or no histopathological evidence has been obtained to differentiate between a retinitis of glycemic origin and one of renal origin Grafe[6] in a study of 1200 diabetics thinks that all cases save the mildest are accompanied with vascular changes and that every diabetic with hypertension of eight years standing develops a retinitis and that vascular changes of the retinal walls are indicative of similar changes in the other vascular areas throughout the body

The weight of opinion seems to be that the development of retinitis in a diabetic indicates advancing vascular disease This vascular disease invariably makes its appearance in diabetics after a certain period Is it due to the hyperglycemia, or is the arterial hypertension due to the hyperglycemia and the arterial degeneration in turn to the hypertension?

It is significant that Grafe advises caution in the use of insulin when severe retinitis is present I believe I have noticed in some instances accentuation of the retinitis after insulin has been used Usually one does not see amelioration of the retinitis though the blood sugar has been kept in normal bounds over a long period

Foster Moore[6] states that the retinitis found in diabetics is the retinitis of arteriosclerosis and the condition of the retinal vessels is a close guide to the condition of the cerebral vessels

Hypertension, vascular disease and renal pathology have constantly been found with retinitis in diabetes The lipaemia, ketosis and hyperglycemia are the products of the disturbed metabolic state we designate as diabetes The retinitis is part of the picture resulting from this disturbed metabolism It means that the metabolic disturbance has so far proceeded in its destructive course that advanced vascular disease is manifesting itself

Willbrand and Saenger discard the term retinitis and speak of retinal angiopathy and state that the retinal angiopathy seen in diabetes is not to be distinguished from that of general angiosclerosis.

De Schweinitz doubts whether the retinitis is due solely to diabetes but is rather due to the combination of retinal angiosclerosis and diabetes He has seen several cases with extensive hemorrhages and in some instances followed by proliferative retinitis Thrombosis of the central retinal vein may occur not as a diabetic lesion but induced by vascular disease in a diabetic person The retinal changes seen in diabetes mellitus may also be seen in diabetes insipidus

Parker[7] mentions glycemic amblyopia. There is a central color scotoma Occasionally hemianopsia may be present The amblyopia may be the only ocular symptom Paralysis of the extrinsic muscles may occur The 6th or a single branch of the 3d nerve may be involved The levator may be involved producing a unilateral ptosis

Xanthalasma may result from diabetes When Xanthalasma is seen this disease should be thought of and a blood chemistry done

Iritis is an occasional complication, there may be hemorrhages into the anterior chamber and fibrous deposits in the pupillary space. According to Klien posterior polar, combined with posterior cortical cataracts unassociated with chorioiditis are significant of diabetes The characteristic diabetic cataract is a rapidly forming one in a young person the subject of this disease Optic neuritis may occur, the prognosis is favorable in cases properly treated

Duke Elder[8] gives us the most acceptable theory to explain the myopia and hypermetropia The following law may be stated—"The refractive power of the eye tends to vary as the sugar content of the blood" There is a tendency to hypermetropia with decreased sugar and myopia with increased sugar It has been suggested that the change in refraction *caused* the diabetes! The following theories are discussed

(1) Dynamic Dependent on the neuro-muscular mechanism (a) Paresis of accommodation This may account for the change in some but not the majority (b) Affecting the external musculature One case studied was due to change in the corneal curvature with esophoria and presumably depended on a spasm of the lateral muscles

(2) Static Dependent on the physio-chemical mechanism (a) affecting the coats of the eye, a shortening of the antero-posterior axis due to a shrinking of the globe from loss of fluid in the vitreous This is known as the soft eye of diabetes and is a terminal event when the tissues have been dehydrated (b) A lengthening of the antero-posterior diameter due to softening and yielding of the sclera (c) Affecting the media generally An index change due to the presence of sugar or other metabolites This is untenable A sugar concentration of 20 per cent would be necessary It does not account for the astigmatism

(4) Affecting the lens Elsching found that while one eye underwent changes the aphakic eye remained stationary It is most reasonable to explain the changes on the hypothesis that they are due to osmotic influence on the disturbance of the water balance of the body that forms so large a part in the general metabolic upset knows as diabetes The normal constituency of the blood is the first aim of the body mechanism To accomplish this with a blood ladened with sugar, fluid is withdrawn from the tissues by osmosis to dilute the blood and polyuria results The net result is to dehydrate the body, hence the polydipsia The eye shares in the dehydration and the tension falls With the increased blood sugar we have—(1) Dilution of the blood by tissue fluids (2) Excretion from the blood of a concentrated fluid with a high salt content and high osmotic pressure (the urine) which is replaced by drinking water. This produces increase in blood volume and decrease in salt content As the sugar content rises the molecular concentration of the blood and tissue fluids fall The lens remains in status quo and is thus bathed by a fluid at a tension lower than its own molecular state Osmotic inequilibrium having been established fluid flows from the lower level, the blood, to the higher, the lens, deforming it and making the eye myopic. The increase in refractive power may be accentuated by a decrease in the index of refraction of the cortical layers as opposed to the harder and more resistant nucleus making the index of the lens less uniform and therefore of a higher refractive power On a fall of blood sugar a reverse osmotic change occurs and some degree of hypermetropia is produced by the transference of fluid from the lens to the blood, the osmotic pressure of which is now raised It is probable that cataract in diabetes may be due to more ready degeneration induced by strain of the deforming force and increased fluid traffic

A case in point is the following—

Mr H L W 53 years of age, occupation banker, First seen in 1923 at which time V O D 20/20 W C — 0.25 x 180

V O S 20/20 W C —0.25 x 180

W S + 1 00 & cyls he could read J 1 with ease

Again seen in March, 1927, when he required a + 1 75 for reading Eye grounds at both examinations being normal On February 9, 1928, he complained of dim vision which in each eye was 20/50 W S —0 75 () —0 50 x 180 =20/15 Eye grounds normal With dilated pupils, however, one could see very distinctly with the ophthalmoscope the nucleus of the lens differing so greatly from the cortex in refraction that at a distance of 12 inches from the eye the appearance of nuclear cataract was simulated On direct examination, however, with this instrument the media appeared quite clear as also with the slit-lamp and microscope The urine showed 3 3 per cent sugar and the blood 153 mgm per 100 c c of blood He was placed in hospital on proper regime and the eyes returned to their normal condition in ten days The vision was 20/15 without correction and the appearance of the lens was normal This case exemplifies Duke Elder's theory of the changes in the lens caused by osmotic variances The following cases are of interest, one in connection with changes in the refraction and one with glaucoma

Mr A C M, Real Estate Operator, age 47, First seen April 16, 1928, complaining of dim vision for distance and near Wearing for distance C — 0 50 x 180 ea For near S + 1 50 & cyls each eye Fundus examination showed retinal edema particularly about the maculae with well marked retinal angiosclerosis There was veiling of the fundus that was diffuse and illy defined There were white, dimly outlined, radiating lines at the maculae which were probably folds in this membrane since they subsequently disappeared.

With the retinoscope only a very dim reflex could be seen The refraction was as follows

V O D 20/30 W C — 0 50 x 180 = 20/ 15 dimly J 1 W S + 150

V O S 20/70 W S + 1 0 = 20/30, J 1 W S + 3 0

He was placed in the hospital for study The sugar in the blood was 192 mgm per 100 c c and in the urine 1 4 grams in the 24 hours He was put on a diet of 74 grams of carbohydrates, 52 grams of protein and 88 grams of fat On May 8, his blood sugar was 140 mgm and his urine was sugar free and

V O D 20/15, accepted no glass,

V O S 20/20, accepted no glass

J 1 W S + 2 00 in each eye

The retinal edema was improved, there was no improvement in the retinal vessels The refractive changes in the right eye were toward hypermetropia as the blood sugar was reduced. The left eye became less hypermetropic at the same time

Mrs J M L Age 52, School teacher Seen April 16, 1928 Complaining of irritation in the left eye with reduced vision

V O D 20/15,

V O S 20/40, accepted no correction in either eye There was a low grade uveitis with deposits on Decemet's membrane in each eye. Tension (Schiotz) in each eye 20 m m Hg On April 30 the tension was R. E 26, L. E. 43 At the first visit she had been put on atropin 1% twice daily This was omitted and pilocarpin and eserin substituted, but the tension still remained up

The interesting point about the study of this case was that she had a blood sugar of 133 mgm and the sugar tolerance curve elevated At 9 A M she was given 100 grams glucose At 10 A.

M the blood sugar was 230, at 11 A M 190 and at 12 M 160 In addition to this, infected teeth and tonsils were removed and a low grade nephritis with generalized arteriosclerosis was observed Was the uveitis due to the foci of infection? Was the nephritis due to the same cause? Was the prediabetes due to the arteriosclerosis and nephritis, to the foci of infection or were the nephritis and vascular disease due to the high blood sugar—the prediabetes? The uveitis is slowly improving Trephining will probably be necessary

Reid[9] remarks that Weir Mitchell said, "It is possible that the long continued presence in the blood of even small quantities of excess sugar may cause in the crystalline lens osmotic changes productive of opacity" He quotes W H Snyder as saying that the anterior capsule is the only one through which entrance is made by fluid to the lens These cells having a selective action, there comes a time when this is lost and then osmosis takes place On the functional activity of these cells depends the period at which the concentration of sugar will affect the lens Focal infection plays an important part in cataract formation in conjunction with hyperglycemia

Benedict[10] observes that insulin increases the peripheral circulation and predisposes to hemorrhage following cataract operations and suggests withholding it for four weeks after such operations

Murphy[11] remarked "No class of patients is more prone to surgical complications, has less tendency to recovery and has less resistance to toxic infection than the diabetic" Later studies have shown that the condition of the urine must not be taken as the sole guide to the patient but that the blood sugar percentage should be known Before operating on eyes a very careful study of the patient is made as matter of routine Focal infection, particularly of the mouth is eliminated Aside from the routine urinalysis which is so essential, a routine blood sugar estimation should be made or better still a blood chemistry

The nitrogen content of the blood may indicate important metabolic or degenerative changes If the fasting blood sugar is increased further studies should be made to determine the glucose tolerance This is very important as incipient diabetes or prediabetes, if one may so term it, may be present for a long time and there be no evidence other than as indicated in blood sugar study and sugar tolerance tests

The ophthalmic surgeon is only too familiar with the cataract case that develops after operation a red, painful, tender and weeping eye, a chronic cyclitis which resists our every effort Undoubtedly some of these patients can be saved by preoperative study of the blood One case of this type operated upon before the blood chemistry was perfected developed such a condition The preoperative study had eliminated focal infection and pathology of the urine The eye dragged on with a low grade cyclitis exhausting the vitality of the patient as well as the surgeon Four weeks after the operation during another complete general study to determine if possible the cause of the cyclitis, glycosuria was found. The patient was evidently diabetic before operation but without glycosuria Proper treatment promptly relieved the eye

Fortunately we do not have to often consider general anaesthetics in ophthalmic operations, when this is necessary in diabetics we should know the Co_2 coefficient and the alkali reserve of the body Foster[12] says patients showing hyperglycemia of 35% of Co_2 combining power of less than 40% cannot be expected to survive surgery

Berkman[13] in his preoperative study investigates the patient for evidence of infection and renal disturbance; renders the urine sugar free as promptly as possible, establishes tolerance roughly, brings the diet to maintenance caloric value and is sure the patient is free from acidosis Special attention is given to the number of days of starvation necessary to clear the urine of sugar as well as the general affect on the patient of radical manipulation of the diet Patients whose urine clears slowly and who complain of marked weakness and other distressing symptoms are carried on medical treatment for some weeks before being operated upon if the circumstances permit Prescribing the diet of such patients is not a mathematical calculation Individuals differ widely in what they can maintain their strength and vigor upon A patient who excretes more than 1 5 grams of ammonia and shows a positive ferric chlorid reaction for acidosis should have more prolonged treatment

Berkman has found the blood sugar estimation only of value in a few cases in which it remained persistently high after the urine was sugar free He depends on fluid by mouth, rectum or subcutaneously in threatened coma, with orange juice up to 250 cc daily

Zimmerman says trauma produced by local anaesthesia has a tendency to invite infection as diabetics may have tropic disturbance

Rountree remarks that renal glycosuria is one of the rarest diseases Even so we should not trust to this rarity altogether in our preoperative study

It is an accepted fact that operations on the eye and perhaps cataract extraction in particular being done under local anaesthesia and calling for a minimum of trauma do very well in diabetics There are a certain number, however, who may leave the hospital in good condition and later develop complications, low grade uveitis or secondary glaucoma for example, which lead to the destruction of the eye More, many more, such complications occur than ever reach the statistical reports so that we are apt to be misled

in such reports and would do well to most carefully study our patients, particularly where a possibility of diabetes exists Adams and Wilder[14] give 100 grams of glucose with sufficient insulin to assimilate it two or three days before operating Patients with adequate sugar reserve withstand operations better than those whose sugar reserve is low The control of hyperglycemia and glycosuria seem to be of minor importance after the operation They speak of "Internal respiration" as being the combining power of the alkalis in the blood with fatty acids with the liberation of CO_2 in the lungs

Mayo[15] in discussing the rehabilitation of the surgical patient observes that fat cannot to any extent be converted into glucose in the body but that proteins can When the latter occurs the excess nitrogen resulting is excreted in the urine. The kidneys may be unable to excrete this excess which accumulates in the blood mostly as urea, less as createnin, producing uraemia A properly regulated diet with judicious employment of insulin and glucose renders the patient with diabetes a good surgical risk in the majority of cases Mayo further remarks that "Someone has facetiously called diabetes a foot and mouth disease!"

Joslin[16] says "The vast majority of persons who develop diabetes are those who are overweight" Many persons with hypertensive nephritis react to the glucose tolerance tests with a hyperglycemia curve indicative of mild diabetes Impaired renal permeability will necessarily prevent glycosuria in many such cases In some individuals with normal blood sugar the renal threshold may be low and they may thus show a glycosuria In hypertensive cases with a diabetic tendency benefit is obtained by limitation of diet and reduction of weight. No such benefit comes from undernutrition in non-diabetic hypertensive cases Indeed much harm may be done this last class of patients by starving them

When there is abnormal hyperglycemia after meals or the glucose tolerance test produces a hyperglycemia exceeding in length and duration the normal, a definite diagnosis of diabetes can be made. It is persons of this type that careful study only will show to be abnormal In these overweight individuals with obstinate eye lesions or anticipating ophthalmic operations, particularly cataract extraction, careful study may prevent disastrous consequences We must recognize the fact that diabetes is more prevalent than heretofore indicated. Diabetes in the stage of simple glycosuria may cause neuritis, optic or general, neurasthenia, feeling of weakness, etc and may in all probability cause retinal lesions and cataract

Illustrating the form of non-glycosuric diabetes Taussig[17] notes a case of furunculosis and one of pruritus ani There was no glycosuria but the glucose tolerance test showed the typical blood sugar curve of diabetes mellitus Such a condition is not infrequent in old cases having a high-grade interstitial nephritis which caused disappearance of the glycosuria The latter case was not of this type having no nephritis and might be considered as being in the pre-diabetic stage They have a strong tendency to the disease and untreated would probably develop it It is obvious that such "pre-diabetes" may be an etiological factor in various diseases such as low grade uveitis, obstinate non-refractive asthenopia and low grade cyclitis following operations A case in point is the following

Mrs X Wife of an Army Officer, 40 years of age, good family and personal medical history For some years she had persistent asthenopia on attempting near work She could use her eyes for only a few minutes Painstaking examination of the eyes showed nothing beyond a moderate hypermetropic astigmatism. The extra ocular muscles, accommodation and the eye grounds including the retinal vessels were normal An equally painstaking medical examination was barren of results Teeth, tonsils and nasal accessory sinuses as well as the genito urinary tract were ruled out A glucose tolerance test, however, showed the "prediabetic curve" and on proper dietary regime she was able in three months to use her eyes all she desired without pain or discomfort

Taussig further remarks that a fasting blood sugar of 125 or post absorption blood sugar of 145 calls for further investigation Children in diabetic families should be investigated by the tolerance test. Blood sugar estimation is the only rational basis on which to diagnose or treat diabetes mellitus In normals following the glucose tolerance test the blood sugar curve rises to the highest peak in half an hour and declines to normal within three hours In diabetes the rise takes two to three hours and the decline four to nine hours

Cammidge thinks there is hyperglycemic diabetes of the pancreatic type and of the hepatic type and of other types The chemistry of these types is not identical In the pancreatic type the blood does not easily coagulate while in the hepatic type it does This first type may account for some of the retinal hemorrhages

Gray Clegg, in reviewing cataract extraction in diabetes at the Manchester Royal Eye Hospital in the last twenty years says the final results were not remarkably below the average A noticeably frequent complication being hemorrhage in the anterior chamber

Here might be mentioned two cases of this type, both mild diabetics of advanced age with the usual vascular changes In both patients on dressing the eye the third day after the operation and while inspecting the eye with the loupe the patients complained of sudden sharp pain and droplets of blood were seen to trickle slowly down the back

of the cornea just as rain drops run down a window pane

Leyton's[18] observations are instructive Glycosuria due to a low renal threshold is variable, depending on the nature of the food In those with a threshold a little below normal the glycosuria is intermittent Glycosuria arises occasionally from sapraemia as may be seen in those having boils Pancreatic glycosuria is modified by alterations in the renal threshold This threshold rises as time passes Emotional disturbance, hyperthyroidism and toxemia may increase the hyperglycemia The absence of glycosuria does not prove the patient non-diabetic, the presence of glycosuria does not prove him diabetic

Nephritis with glycosuria may be due to primary nephritis with glycosuria due to renal deficiency, or to a nephritis caused by a pre-existing diabetes In nephritis owing to damaged renal epithelium there may be glycosuria with normal blood sugar More commonly there is hyperglycemia and glycosuria, the former possibly caused by suprarenal oversecretion excited by retained wastes

THE RELATIONS OF THE MEDICAL PROFESSION TO THE PUBLIC*

By WALTER L NILES, M D, NEW YORK, N Y

IT is obvious to any thoughtful person, whether layman or doctor, that profound and highly significant changes have developed in the relations between the public and the medical profession For decades and even centuries, changes were insignificant, but in recent years, particularly since the beginning of the twentieth century, they have been so rapid and so startling that both of the parties concerned find themselves somewhat dazed, and in some instances apprehensive, concerning the future It will be my purpose to examine into some of the causes of the current unrest, to prognosticate the future, and to possibly suggest cures

In the preface to his admirable book "An Introduction to the History of Medicine" Dr Fielding Garison writes as follows "The history of medicine is, in fact, the history of humanity itself, with its ups and downs, its brave aspirations after truth and finality, its pathetic failures The subject may be treated variously as a pageant, an array of books, a procession of characters, a succession of theories, an exposition of human ineptitudes, or as the very bone and marrow of cultural history As Matthew Arnold said of the Acta Sanctorum, 'All human life is there'" We thus see that medicine always has been and always will be woven into the lives and souls of mankind Disease will threaten, illness must be cured, and health must be protected always It is impossible to picture a state so idyllic that the people will not need and demand the benefits of the science and practice of medicine Personal health touches the very foundation of the economic stability of the state, and it is safe to predict that in the near future it will not only, as at present, more or less sympathetically tolerate medical research, but it will demand investigations into the nature of disease and, let us hope, be prepared to foot the bills It is therefore obvious that society needs doctors, and it is equally clear that doctors need patients, for doctors are dependent upon the public for support

Having evolved from witchcraft and having always been shrouded in mystery, medicine and its apostles have been difficult of understanding by the laity Although our system of ethics provides primarily for the interests of the patient and for public health, we frequently encounter impatience when we adhere to the letter of the law

* Read at a meeting of the New York Physicians' Association on December 19, 1928.

prescribed by our wise men Our training, our responsibilities and the mode of life which is required of us as practitioners of the science of medicine, tend to make us differ in our reactions from the rest of society, and we are apt to be regarded as a bit different if not a little queer, lay managers of medical institutions consider us difficult to manage. We, on our part, sometimes feel that society is strangely unappreciative of our efforts, and we occasionally protest when the lawmakers impose restrictions upon us or accord recognition to cults which we know do not operate for the benefit of society However, the interests of society and the medical profession are so closely identified that we must come to a mutual understanding and together help each other

A casual survey of recent periodicals, both popular and thoughtful, clearly indicates that considerable fractions of the public are dissatisfied with the medical profession They feel that they are not receiving all that they should get, and that what they do get costs too much Whether right or wrong in this feeling it is of vital importance for us to heed the cry, for it is, to my mind, perfectly clear that we are servants of the public and if our present methods do not satisfy, it will sooner or later adopt measures which will require us to provide it with what it wants The profession usually protests against new methods of providing adequate medical service on the ground that it curtails some doctors' incomes The argument is fallacious and mistaken The sole answer to any such proposal is whether it makes a better provision for public welfare than do the existing means It is said that the profession constantly endeavors to eliminate itself by preventing disease While it is true that the control of certain infectious diseases has curtailed the demands for medical service in that particular field, it is equally true that every advance in public health welfare has necessitated more service from the profession, so that today there is a greater per capita demand for medical service than ever before It is the aim of the socially-minded, both within and outside the profession, to extend adequate care of the sick and modern preventive measures to those who now do not receive their benefits in full This is sound economy from the standpoint of the community, and we of the profession will therefore be compelled to provide such benefits It may be safely asserted that the best interests of the profession indicate that we should promptly and whole heartedly cooperate in every such movement. Moreover they should be initiated by us whenever the opportunity presents itself and thus remove the charge often made, and for which there has been just cause, that it is necessary for laymen to spur the profession into discharging its full duty

Another criticism of the profession is that medical service costs too much, and that the ordinarily self-supporting family becomes impoverished when it meets with illness It is certainly true that competent medical service is expensive and is, I fear, likely to become more so if our knowledge of disease continues to expand Yet I doubt if it has increased out of proportion to other necessities of life, medicine has to compete with the luxuries rather than the necessities The public has been impressed with the large incomes of some of our colleagues and believes that practically all doctors get rich, despite the fact that careful studies show the average doctor's income is pitifully small compared with the average incomes of other professions, business, and trade It is of course obvious that unless the average doctor can earn a sufficient income to permit him and his family to live in circumstances comparable with others of equal education and culture in his community, the profession will cease to attract desirable young students We are, however, not yet confronted with such a situation as the number of applicants to our medical schools far exceeds the available facilities, and I am confident that provision can and will be made by the universities so that no shortage of physicians need be feared even with the inevitable increase in the population The high cost of medical service is largely attributed to the increase in specialism, and the necessity for more frequent use of the specialists' service which has been brought about by the vast increase in knowledge pertaining to medicine It is certainly true that it is no longer possible for one man to become skilled in all or several of the divisions of medicine, and that the specialist is essential, both in practice and in research Specialism has been largely responsible for the great advance in medicine and should therefore be encouraged, but it will be necessary to impose certain requirements of education and experience to protect the public and the profession against the pseudo-specialist. It has been the good fortune of our friends who are specialists that it is far simpler to become proficient in the diagnosis and treatment of a limited portion of the anatomy than it is to acquire a broad understanding of the body as a whole That is, however, an argument for encouraging specialism

Does medical service cost too much? In comparison with other recognized necessities I doubt if the proportionate cost is excessive. If the public could be educated to an understanding of the economic necessity for maintaining health, it might then assign a fraction of the annual income to medical care. And if, when it was not used, it would be deposited in a savings bank and kept for a rainy day, the amount when required would not seem excessive and the doctor's bill might be paid The difficulty is that it is generally assumed that health will be maintained somehow, and when disease develops, it is looked upon as an accidental disaster outside the normal course of life "Public health is purchasable." Is it too much to ask that the public lay aside ten per-

cent of its income for medical service? If it is conceded that the foundation of economic safety is built on health, I do not believe that proportion is excessive

The public also complains that there are no family doctors, only specialists, which is of course not true There are plenty of family doctors, but there would be many more and the laity would know more about them if it would employ them as such, instead of seeking their services only in emergencies or when it admits that it cannot assign its symptoms to the field of some specialist The people who receive the best service from the profession are those who attach themselves to some family doctor and remain loyal to him These wise ones ask him whether they shall go to a specialist, and if so, to what one They thus secure his cooperation with the specialist which is invaluable in any condition whatsoever it may be We doctors only know the appreciation which we have for loyalty on the part of our patients, and that the feeling that the patient and his family have confidence in us inspires us to our best endeavor Many times have doctors said to me that "patient so and so has been loyal to me for ten or twenty years and I would do anything for him"

The profession is criticized because it has not taken a more active part in initiating and promoting health movements which have been so prevalent It is pointed out to us that the earlier ones were largely developed by lay people, and that the profession did not heartily cooperate in them We must admit the indictment, but we have largely overcome our early inertia and I feel confident that in the future the public will have little cause for complaint in that respect, indeed it may shortly begin to complain of our over-enthusiasm and aggressiveness in forcing prophylactic measures upon an indifferent populace In any event, it should not forget that the discoveries and observations upon which health movements are founded have come only from the profession, and that a reasonable division of labor requires that the public shall participate in protecting against disease

A matter of vital interest to both the medical profession and the public is that of the secret division of fees, commonly called fee splitting All systems of medical ethics have invariably proscribed this practice as inimical to the best interests and welfare of the patient, it introduces self-interest on the part of the attending physician and may thus deprive the patient of an unprejudiced opinion, it may also interfere with his securing the best available talent to minister to his particular malady, and it always leads to disharmony among the practitioners of any given community While the practice has undoubtedly prevailed among certain sections of the profession, it has seldom been openly advocated because of the stand taken by organized medicine Convictions for splitting fees have been infrequent, though often a matter of common knowledge, because of the difficulty in securing evidence when two parties have conspired to commit a breach of the code of ethics I suspect that the practice is spreading, and recently certain groups in the profession have openly advocated division of fees under certain circumstances The question is therefore squarely before the profession and as it directly involves the public welfare, it must be squarely met

So far as I am aware, the sole reason for advocating a division of fees is that the family physician feels that he does not receive remuneration commensurate with the importance of his services when compared with the remuneration received by the specialist This is true in many instances For example, the family physician must frequently exercise the highest skill and display rare judgment in deciding whether a child is suffering with acute gastro-enteritis, which is a comparatively mild affection, or acute appendicitis which if overlooked or neglected for even a few hours, may cost the patient his life The doctor's responsibility is exceedingly heavy and he is frequently denied the privilege of consultations which he desires He must spend considerable time, and at once, whatever his other appointments may be, administering treatment and carefully watching the effects If he properly diagnoses the condition as acute appendicitis, he calls a surgeon who usually arranges to operate in some hospital with which he is connected The surgeon's expenditure of time and effort is relatively slight, and the operation and after care may take little more of his time than was expended by the physician, and for this, being a specialist, he receives a fee from ten to one hundred times as much as the physician receives And furthermore it often transpires that the surgeon also gets the meed of praise, as well as being more likely to collect his fee

This is all wrong, but in my opinion the wrong will not be cured by dividing the surgeon's fee either openly or in secret There can be no compromise on fee splitting, for it is basically wrong It is, however, the duty of the leaders in the profession to provide information to the public so that it will be educated to an appreciation of the high degree of skill and the heavy responsibility exercised by the attending physician in the proper utilization of the specialist's skill and services When the public is educated to such an appreciation, it will cheerfully pay a reasonable fee to the man on the firing line (the first line of defense against disease), and if it should subtract that sum from the specialist's fee, it would not, in my opinion, be inappropriate.

The training of physicians, as well as their daily work in practice, tends to make them individual-

ists, and the profession has been slow to adopt the methods employed by business and other professions to conserve time and energy and thereby increase their output. Until recently mass production and business methods have not been utilized. Bearing in mind the basic principle of medical practice, the welfare of the public, it remains a question whether they should be extensively adopted by the profession. There is no doubt that our most highly trained and most experienced doctors often waste their time in making routine examinations and treating common minor disorders. Yet to the patient his ills are never trivial and so far as possible he demands the best available talent. To meet these objections and to make specialist's advice more readily available, group practice has been developed throughout the country—less in New York City than elsewhere. In the instances where groups have been formed for the purpose of rendering better service and not with the object of making more money, they have been useful and economical in handling those cases which require extensive diagnostic surveys. It is, however, doubtful if they can successfully or efficiently care for the mass of general practice, particularly when the patient is ill at home. It has been estimated that 85 per cent of all cases can be properly handled by competent general practitioners, and it is therefore doubtful if groups will arise except in the larger cities, and then chiefly to serve as consultants to the family physicians. In any event it appears improbable that they will be utilized to such an extent that the general cost of medical service will be materially lessened. It seems to me that a better method is for those doctors whose services are in great demand to employ junior assistants to relieve them of much of the routine burden, they to exercise supervision and consult with the junior. In this way the younger man receives excellent training and lays a foundation for his own practice in much the same way the apprentices did years ago.

The welfare of the public requires the maintenance of hospitals for the care of the sick poor as well as for the sick rich. It requires that they shall be well equipped and that the professional services rendered shall be of first rate quality. The medical profession has always cheerfully accepted this responsibility and when a new hospital is contemplated, the sponsors entertain no doubt that the best talent can be readily secured. This is as it should be. If the hospital is designed to include the care of private patients, the attending professional staff is offered a splendid opportunity to centralize practice, and while discharging obligations to the free patients can also do remunerative practice. But even the city hospitals which do not admit private patients attract the best equipped men in the profession. The reason is that the hospital physician is in a position to take advantage of the very best opportunities for gaining experience and education. I find no justification for the plea that such doctors are making great sacrifices in caring for the poor, or that because of the large amount of time which they give to charity cases they must demand large fees from the rich. The hospital physician, if he has the true physician's zeal, receives much more than he gives, and he seldom relinquishes his opportunity until forced to do so by an age limit or impairment of his health.

Why then should not every legally qualified physician be permitted to send his patients either to separate rooms or public wards, and then carry out any measure of diagnosis and therapy he considers desirable? This is the plea advanced by the advocates of the "open hospital." I am convinced that such a procedure would not operate to the advantage of the patient, the hospital, or the profession. The Public Health Relations Committee of the New York Academy of Medicine is engaged in a study of the question, and I am permitted to read extracts from the tentative report. A summary of the conclusions is as follows:

"Of all the large cities, New York provides the greatest opportunity for institutional affiliation of physicians. It is no exaggeration to say that any man of ambition, industry, and ability to cooperate with others can secure a position in a good hospital, if he is willing to serve the necessary apprenticeship.

"Some hospitals are overstaffed, others can add to their attending staffs without interfering with the present efficiency of their work. A ratio of one member of the attending staff to every five ward beds prevails in many of the best organized hospitals.

"A large proportion of our hospital facilities are in the municipal hospitals to which no private patients are admitted. Those who attend the nonpay patients in the municipal hospitals seek other appointments in voluntary hospitals where they can carry on their private work. From the community point of view and that of medical efficiency, overlapping multiple appointments are unnecessary and undesirable, except one appointment in a private hospital in addition to service in a municipal hospital.

"An open hospital cannot be administered as successfully as a closed hospital, and the patient is better served in the closed hospital than in the open hospital.

"The advantages of professional education claimed for the open hospital are more than offset by the disadvantages associated with this type of hospital organization.

"The existing opportunities for study and research are not sufficiently utilized by the medical profession. Under the circumstances the sincerity of the clamor for open hospitals, insofar as it concerns opportunities for research and education, may be questioned.

"The union between the out-patient department and the hospital is not as close in many institutions as it should be for the benefit of the patient as well as for educational opportunities and advancement of the profession

"Insofar as New York City is concerned, the open hospital plan is unnecessary, undesirable and impractical at the present time All that is claimed for the open hospital can be obtained equally well and much more simply by the modification of the present system"

The recommendations which are proposed are as follows

"1 All hospitals which are not fully manned should be urged to increase their staffs to a point compatible with greatest efficiency

"2 In principle, no member of the attending staff should have more than one active hospital appointment, with the exception of those who serve on the visiting staffs of municipal hospitals where no private patients can be accommodated

"3 When a patient is sent to a hospital by a physician not on that hospital staff, every effort should be made by the hospital authorities to continue the contact between the patient and the physician who referred the patient In cases of patients occupying private or semi-private accommodations in the hospitals, the family physician making professional visits may with propriety charge for his services

"4 Courtesy privileges granted by hospitals should be made available to the greatest possible number of physicians who have proven themselves properly qualified

"5 The plan of making places in hospitals for volunteer physicians should be seriously considered and adopted wherever possible

"6 The dispensary or the out-patient department should be more developed as a place for graduate teaching and that it should be intergrated with the work of the hospital along the lines laid down in the body of the report"

Medicine concerns itself with the prevention and cure of disease In order to achieve progress and continuity it must provide for researches into the nature of diseases and for teaching the beginners in the science It may no longer be anticipated that the solitary worker with scant equipment will succeed in making important additions to the knowledge of disease, and it is therefore necessary to provide a certain number of physicians with time and opportunities sufficient to engage in prolonged and continuous studies A now considerable group has been developed who are giving all of their energy and time to the study of problems relating to medicine, and in their hands and brains rests the scientific future of medicine It is obvious then that any plan for medical advancement must provide liberally for these academic workers Up to the present time this has chiefly come from private benefactions and they may multiply sufficiently to care for the future needs in this vital section of medicine. If, however, they do not, the state must be prepared to support medical research, and the public should be educated to appreciate the necessity for continuing and expanding the research facilities of all medical institutions

The history of medicine shows that the public has had little cause for complaint concerning the skill, industry, and idealism of the profession We are sometimes just a bit apprehensive about the ideals of some of the younger members, but we have faith that they will not be engulfed in the tide of materialism which was precipitated by the great war We ask the public to cooperate with us and manifest its confidence by supporting our ideals and efforts

What of the future?

Through education better understanding will be developed between the public and the medical profession This will come chiefly from the profession which will gradually emerge from its individualistic isolation and freely spread information concerning public health welfare and assume the leadership in providing the best possible medical service for all sections of society

Medical service will not become cheaper, it will probably become more costly The profession should make every effort to conserve its time and equipment The public must realize that health is essential for economic security, and that good health cannot be anticipated without prophylactic effort The public will anticipate a certain amount of illness and will be prepared to pay for it as well as numerous luxuries

Secret division of fees will not be countenanced by the profession The public will, however, learn better to appreciate the value of the services rendered by the attending physician and will pay him accordingly, possibly at the expense of the specialist.

The "open hospital" plan will not be generally adopted but the hospitals will be developed into community health centers and will extend the opportunities which they possess to more of the profession as well as the public It is hoped that more physicians will take advantage of these opportunities than has been the case in the past

The benefits of medical science will become available for all sections of the populace Medical service, especially prophylactic medicine, will be increased through official and voluntary agencies, clinics, and whole time physicians employed by industries This will not mean state medicine, and organized medicine should foster and participate in the movement, because, if for no other reason, it will bring more money into the profession

The future of the profession was never so bright as today The physician of the future will be more highly respected and appreciated than

ever before For any young man possessed of a reasonable degree of ability, breeding, and industry, medicine, beyond any other calling, offers a prospect for achieving intellectual satisfaction, an unparalleled opportunity for service to mankind, and the assurance of economic security

---

MAILABILITY OF MEDICAL LITERATURE ON THERAPEUTIC ABORTION AND CONTRACEPTION

By ROBERT L DICKINSON, M D, F A C S, NEW YORK, N Y

Our postal laws, if enforced with formal strictness, would bar from the mails or express any medical book or medical journal which provides doctors with information on methods of interrupting pregnancy to save life, as in the case of pernicious vomiting or uremic convulsions

Section 211 of the Federal Penal Code says in part " .. every book giving information directly or indirectly by what means any act or operation of any kind for the . producing of abortion or how abortion may be performed is declared non-mailable matter Whoever shall deposit or cause to be deposited for mailing or shall take from the mails anything (thus) declared to be unmailable shall be fined not more than $5,000, or imprisoned not more than five years, or both "

Our postal laws, if strictly enforced, would bar from the mails or express any medical book or medical journal which provides doctors with information on methods whereby sex union is safeguarded in the case of patients who must postpone pregnancy because it would endanger life The same Section (211) reads "every letter book, pamphlet giving information directly or indirectly by what means conception may be prevented .is declared to be non-mailable matter Whoever shall deposit or cause to be deposited in the mails or shall take from the mails (such matter) shall be fined not more than five thousand dollars or imprisoned for not more than five years, or both "

I drew attention to this law in my paper on Control of Conception, published in the NEW YORK STATE JOURNAL OF MEDICINE for May 1926, p 596, stating that public opinion seemed to be against enforcement of this part of the law, because no action had been taken on my report on technique in "Contraception, a Medical Review of the Situation," printed in the *American Journal of Obstetrics and Gynecology*, VIII, 5, November 1924 and in the transactions of the American Gynecological Society for 1924 I said further that this was the first extensive test of the attitude of the post-office In this I was mistaken I should have remembered the excellent monograph of thirty-one pages by Dorothy Bocker, M A, M D, entitled "Birth Control Methods," privately printed by the "Birth Control Clinical Research, 104 Fifth Avenue, New York City" in February 1924 I am informed by Mr Dudley Siddall that 5903 copies were mailed to doctors who ordered them in answer to a circular, and that the name of the physician and a serial number stood on each fly leaf His letter also states that the Post Office investigated, that as the publication was "non-commercial" (at the "nominal price of $1 00") and author and recipients licensed physicians, the officials seemed to be satisfied with the good faith of the sponsors (the American Birth Control League, under Mrs Sanger's presidency), and finally that mailing continued for seven or eight months without interference This is worthy of record as it is historically the first example of a considerable case history report on contraception that goes into careful detail, covering some 1,458 patients The first real report on *follow-up* is that of Dr Hannah Stone from the same clinic, published in the *Medical Journal & Record*, March 21, 1928.

Thus physicians are law breakers who in this country secure medical texts containing information necessary in their practice for the purpose of saving life or safeguarding health when endangered by pregnancy under certain conditions The Custom House bars certain books on birth control except when intended for medical libraries It will not pass a shipment of pessaries, even for birth control clinics like the one at Johns Hopkins, or for use in nine leading hospitals in New York City where contraceptive treatment is given However, now that good pessaries are made in this country, and there has been no interference with mailing to doctors, this is no great hardship The legal ban on written scientific instruction is the chief absurdity in this situation

SUMMER MEDICAL NEWS

This JOURNAL emphasizes news of the activities of other state societies and its department, "Our Neighbors," carries six or seven pages of abstracts of descriptive articles appearing in other State Journals These abstracts are printed in order to inform the medical leaders of New York what those of other states are doing in a practical way The editors of this JOURNAL are especially interested in the annual reports of officers, the proceedings of Houses of Delegates, and minutes of official conferences, for these are milestones pointing both the way and the extent of medical progress

It is gratifying that during the quiet summer season all the State Journals are carrying an increasing amount of news of activities which are of interest to the leaders of the Medical Society of the State of New York

THE VOICE OF THE MEDICAL PROFESSION

Every human organization has a creed and a ritual even though they are not conscientiously recognized by the members The medical profession has both a creed and a ritual

The creed of the medical profession is expressed in the Oath of Hippocrates, in the Code of Ethics of the American Medical Association, and in the principles of professional conduct of the Medical Society of the State of New York

The ritual of the medical profession is unwritten, but, like the English Constitution, it is the more powerful because of its mysterious tradition which can neither be proved nor disproved by direct quotation The records of every medical society meeting contain appeals that its members follow the customs and principles of action established by years of usage

Medical men are bound by strict rules which have the force of a ritual These rules are the forceful expression of ideals which individual physicians can seldom exemplify to their full degree in their daily practice

The people generally do not understand the reason for some of the details of the medical creed and ritual, and even medical men themselves are sometimes inclined to ignore them when they interfere with the modern practice of scientific medicine, for the evolution of the science and art of medicine, especially in its preventive forms, has overthrown some of the cherished interpretations of the older medical creed and ritual Gone are the pompous manner, the gold-headed cane, and the dignified dress of the physician of a century ago Gone, too, are the age of mystery of the awesome consultation when the medical oracle spoke excathedra from behind closed doors by the mouth of the senior doctor Gone also are the days of polemic medicine when physicians condemned the homeopaths and electics publicly and consulted them in private Gone too are the days of mystery when doctors feared to subject either their ignorance or their knowledge to the criticism of an enlightened public. But in the place of mystery and secrecy medical publicity has come into existence, although medical men have not yet entirely grasped its significance

Medical publicity has been defined in clear terms by the Executive Committee of the Council of the Medical Society of the State of New York as follows "Medical publicity is that which is educational and deals with the medical profession in its entirety, while medical advertising appertains to the medical publicity which deals with the individual and may be used to his or her personal advantage" (See the NEW YORK STATE MEDICAL JOURNAL of May 1, 1929, page 573) This definition was adopted by the House of Delegates as recorded in the minutes printed on page 828 of the July first Journal

The occasion for stating the newer distinction between medical publicity and medical advertising was the interpretation of Section 31 of the Principles of the Professional Conduct of the Medical Society of the State of New York, which was adopted May 21, 1923, and which reads "Physicians should not make use of special cards or any other form of advertisement for the purpose of inviting attention to themselves, they shall not boast of cases, operations, cures, or remedies, nor aid or permit the publication of any of the foregoing in the public prints"

Narrow interpretations of this section have been that a physician shall not knowingly permit his name to be used in newspapers in connection with any case which he treats, or any public health movement which he sponsors, and that he shall not sign an article which he may have written for the education of the people An extreme interpretation of the section is that a physician shall not lecture on medical matters in his own community, although he may do so in another locality where he cannot profit by the fame and advertising that may come to him

Progress in the practice of medicine has demonstrated the value of educating the people along medical lines, especially since cultists and quacks have carried on extensive campaigns alleging the falsity of the basis of medical practice, and the scientific basis of their own narrow methods

Progress in medicine has consisted largely in pushing back the time of diagnosis to the preclinical stage of a disease. This means that the patients must be educated regarding the signs and symptoms which are suggestive of disease It means too the people who are entirely well shall give heed to the community measures for the prevention of communicable diseases and the promotion of community health The prevention of disease consists principally in the medical education of the people, and medical education is a form of the practice of medicine The physicians of every community are the natural teachers of medical subjects to the people, but the work is too great for the physicians to carry on as individuals The leadership in medical education belongs to the medical societies, especially to those of the counties and the State Moreover, the medical societies can only give advice as to how the educational work shall be carried on The execution of the work belongs principally to lay helpers, just as the actual care of the sick belongs to bedside nurses who act under the immediate direction of the physicians Some of the educational helpers of the physicians are

1 Officials in departments of health

2 Public health nurses

3 Teachers and physical trainers in public schools

4 Leaders in lay organizations, such as parent-

SUMMER MEDICAL NEWS

This JOURNAL emphasizes news of the activities of other state societies and its department, "Our Neighbors," carries six or seven pages of abstracts of descriptive articles appearing in other State Journals These abstracts are printed in order to inform the medical leaders of New York what those of other states are doing in a practical way The editors of this JOURNAL are especially interested in the annual reports of officers, the proceedings of Houses of Delegates, and minutes of official conferences, for these are milestones pointing both the way and the extent of medical progress

It is gratifying that during the quiet summer season all the State Journals are carrying an increasing amount of news of activities which are of interest to the leaders of the Medical Society of the State of New York

MEDICAL PROGRESS

Treatment of Permanent Arterial Hypertension.—Ch Achard states that it is useless to think of a remedy which will permanently lower the blood pressure in permanent hypertension The rise in the pressure may be compensatory and in such cases the best we can do is to prevent an abrupt increase of pressure There is a hygiene of hypertension which comprises rest in bed, which will secure a reduction after several days An occupation must be chosen which will not cause great fatigue, and one must avoid long walks, and agitation of any kind Meals should be small, meats cut down, and when obesity is present one should diet for that condition The amount of salt permissible is a subject of differences of opinion According to some observers, salt can raise the blood pressure, possibly through provoking thirst and ingestion of fluids Drinks of course are to be cut down to 1200-1500 cc in 24 hours Mineral water cures are therefore of questionable value Coffee and alcohol are prohibited Indications for drug treatment comprise the use of diuretics, but this should not be overdone and it is best to restrict these remedies to cases in which the elimination of urine is below normal In some of the patients the urine is thin and pale and diuretics are of course contraindicated Sudorifics and purgatives are less valuable although laxatives are often required One of the best methods of depletion consists in repeated small venesections Patients can benefit by short walks or light exercise, massage, out-of-door life, and an even climate Baths in carbon dioxide gas are valuable for producing peripheral vasodilatation Electricity in any form is of small value in permanent hypertension and hot baths are contraindicated Of actual drugs enumerated are the nitrites, hepatic extracts, antispasmodics, etc , while in acute crises we have venesection, lumbar puncture, amyl nitrite, and trinitrin When cardiac failure is threatened heart stimulants are required and renal failure also calls for special measures —*Le Progrès Médical,* May 11, 1929

Congenital Stenosis of the Aorta—Torlais, Trocme, and Dufour describe a case of this condition which was complicated by multiple emboli The patient was a boy of 16 who fell in a coma without apparent cause On recovery the right side was seen to be paralyzed and the patient was aphasic In the course of a general examination the cardiac area was found much amplified and there was a double murmur at the aortic orifice The blood pressure was 100 There were no evidences of cardiostasis When the physician was summoned during the night the boy was found in a semicoma with signs of meningeal irritation As there was no tendency to improve under palliative treatment lumbar puncture was practised There were no evidences of tuberculous meningitis and the Wassermann was negative The left arm was showing some contracture and later became cold and livid, cadaveric in its suggestion Treatment had consisted in opiates for the agitation and restlessness, and cardiac stimulants Death took place on the 15th day, the arm being in a gangrenous state An autopsy was not permitted, but the state of affairs seems to have been obvious, to wit, a congenital stenosis at the aortic orifice and the superaddition of multiple emboli The usual cause of aplasia of the aorta is given as syphilis but in the patient's case the evidence is lacking The father was an alcoholic who had more than one attack of delirium tremens The other children in the family were free from stigmata The first embolus was that in the brain with its resulting paralysis and aphasia, and the second took place in the left arm This tendency stood in no essential relationship to the aortic lesion although that of course was a factor, the authors suggest that an infectious element was present and connect it with a recent attack of influenza In this case, despite the prolonged aortic stenosis there was no aortic regurgitation and the only phenomena of stasis were in the pulmonary system (passive congestion of the lung bases) —*Le Bulletin Médical,* May 1-4, 1929

Septic Sore Throat.—Prof W Uffenorde of Marburg adds to the number of papers on this subject which have recently appeared in Germany and gives an outline of four personal cases Of this number none seems to have been of the dreaded thrombophlebitic type and all of the cases were sporadic in incidence so that there is no connection with the epidemic septic sore throat seen in the United States The first patient merely developed a suppurative lymphadenitis in the regional glands—analogous cases of lymphatic propagation of a simple tonsillitis have recently been reported —the general symptoms of sepsis coexisting, although not of a severe type Case II in an old woman was at first taken for mumps following a recurrent angina The swelling subsided, but following peritonsillar swelling an

teachers associations, anti-tuberculosis societies, and child welfare committees

5 Newspapers

This list might be extended to great length The people now recognize the great importance of community health measures to such an extent that any news of a public health nature is featured by newspapers The editors of the daily papers are concerned primarily with the kind of news which the people want to read, and the space which they give to health items is proof of the eagerness of the people to learn more about health and sickness, and to vote for the support of public health measures

Both the news items and the advertisements in the newspapers emphasize the authority of the voice of the medical profession An obligation rests upon the doctors of every locality to make their voices heard throughout the community Physicians throughout the nation have evolved a standard method of popular education as follows

1 The unit shall be the County Medical Society

2 Medical education work shall be done by committees composed of physicians who are specialists as writers, speakers, organizers, and general medical leaders

3 The names of these specialists shall be kept prominently before the public in order that popular medical education may be a concrete, present reality, instead of a far-off abstraction for which no one is responsible

The voice of the medical profession in its greatest power issues from the mouth of the practising physician who writes, speaks, and acts in the name of his County Medical Society

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO

Association of State Medical Journals This JOURNAL for August, 1904, contained the following editorial on the proposal to form an association of State Medical Journals

"Representatives of the State Medical Journals, who were present at the Atlantic City meeting, practically decided that an association of the State journals would be a strong bond of sympathy and good will, after every point of view was fully discussed the preliminary articles of association were prepared and final agreement deferred until next year As these are of special interest to the members of the Association, it is desirable a full expression of opinion should be secured

PRELIMINARY ARTICLES OF ASSOCIATION

"The name of this Association shall be 'The American Association of State Medical Journals'

"Its purpose shall be to federate, for mutual encouragement, support and business interests, the journals now published by State Medical Associations, or which may hereafter be so published, only journals published or controlled by State Medical Associations shall be eligible to membership

"Its meetings shall be held annually at such time and place as the American Medical Association may meet

"This Association makes the following declaration in regard to advertisements No State Medical Journal shall accept an advertisement of a medicine which is not ethical To be ethical in the meaning of this declaration the product advertised must have published with it not only the names of its constituent parts, but also the amount of such constituents, so that a definite dosage can be determined Further, such product must not be advertised to the lay public through the secular press

"In case a product is advertised under a copyrighted name, the manufacturer shall furnish with it the proper chemical name and if not patented then also the process of manufacture.

"All advertisements not covered by above paragraphs, or which contain extravagant and improbable claims, shall be submitted to the executive committee for approval before they can be accepted

"Editors of State Medical Journals and members of Publication Committees of State Societies shall be included in the membership of this Association"

matter of fact was excluded from the present series Autopsies on numerous influenza victims have never shown the complication of appendicitis—*Münchener medizinische Wochenschrift,* May 10, 1929

The Place of Fungi in Modern Medicine—Fred D Weidman, writing in the *American Journal of the Medical Sciences,* June, 1929, clxxvii, 6, discusses the various organic systems in their relation to fungous disease, thus demonstrating the importance of fungi in modern medicine. Among the outstanding mycological advances, from the diagnostic standpoint, we have the waxing rôle of pseudotuberculosis, the ubiquity of dermatophytosis, and the possibility of yeast cells being present in bone abscesses and meningitis Physicians should recognize that almost every organ and every kind of animal tissue is liable to fungous infection, they are not addressing themselves seriously enough to the situation The average laboratory man is largely at fault for our mycological backwardness, because he is not adequately trained in mycology In the treatment of fungous infection, if there is one most useful agent it is iodine Since the advent of the Roentgen rays these are commonly used in conjunction with iodine The latter can be administered in the form of potassium iodide or of Lugol's solution The dosage should be large It is possible, beginning with the usual 5 or 10 grains three times a day, to increase to as much as 120 grains three times a day In treating sporotrichosis, Shelmire administers as much as 10 c c of Lugol's solution, diluted by 100 c c of physiological salt solution, and has had striking results Thallium acetate has been found valuable in the treatment of ringworm of the scalp Given orally, 8 mg per kilo of body weight, it causes falling of the hair in sixteen to eighteen days In the superficial dermatoses, tincture of iodine and salicylic acid ointment are effective Dermatophytosis in other regions of the body than between the toes usually yields to lotions or to ointment of salicylic acid, ammoniated mercury, or other fungicides Tartar emetic, administered intravenously, beginning with 3 c c of a 1 per cent solution and increasing up to 10 c c, has been life-saving in cases of coccidioidal granuloma, a disease which has hitherto invariably proved fatal

Symptomless Infection—Professor W Kolle states that most infections may exceptionally pursue a symptomless course This is revealed for example by certain skin tests when positive, by our knowledge of disease carriers, and by animal experiments In the case of tuberculosis we are only seldom justified in the use of the term symptomless or latent, for nearly always there are symptoms of some sort Syphilis, on the contrary, we now know to pursue rather often a symptomless course, for positive Wassermanns are found in individuals in apparent health and in animal syphilis there may be no general symptoms The author has shown the existence of a symptomless superinfection with syphilis The subject who originally has had a latent syphilis may contract a fresh infection without symptoms and may transmit the disease to others The mouse, now much used in experiments with the treponema may be infected syphilitically and remain syphilitic yet show no symptoms and live out its span of life. It is important to know that the organism can persist indefinitely in the brain of the animal, thus perhaps throwing light on human paresis The victim of late syphilis has often denied positively any history of a chancre, thereby causing the profession to regard all syphilitics as liars, but the author believes that many of these men were entirely unaware of their infection which had been symptomless up to the time of the development of tabes, paresis, aortitis, etc Our knowledge of immunity in man must receive a jolt from these researches on animals, for we must realize that there is a true and a false immunity This peculiarity of the treponema, the author says, probably extends to the entire group of spirochetal diseases—*Schweizerische medizinische Wochenschrift,* May 18 1929

Diagnosis of Rapidly Fatal Diseases of Early Childhood—Professor K Blühdorn refers to illnesses that strike down a healthy child and destroy it in a few days The first example cited is heat stroke in which life is ended by convulsions Thymic death is then mentioned and in this connection a peculiar cardiac condition, hypertrophy with interstitial myocarditis, is referred to Other fourdroyant diseases are epidemic meningitis and the bulbar form of poliomyelitis When a child is suddenly smitten a diagnosis between these several conditions must be made and this is often a most difficult task, while frequent failure to obtain autopsy makes it impossible to confirm the diagnosis Interstitial myocarditis is a condition but little known and the author has found reports of five cases only in which the diagnosis was confirmed by autopsy This affection has probably been included in the picture of thymic death The child is attacked with tachypnea with slight cyanosis, is prostrated yet very restless, and vomits On physical examination the area of the heart is found widened, especially to the right, with the liver enlarged from stasis The children at-

abscess developed at the upper mediastinal region This was evacuated and the tonsil of that side enucleated, when pus was found in the peritonsillar space The fact that the lower abscess was encapsulated doubtless saved the life of the woman The third patient was a girl of 14 with history of tonsillitis and secondary nephritis She developed a retropharyngeal abscess Both the preceding patients showed clinical evidences of sepsis although there is no mention of positive blood findings The fourth case ended fatally, the patient was a man of 34 After an ordinary angina had set in pus formed and was evacuated from the peritonsillar and retropharyngeal spaces A phlegmon then developed at the side of the neck and the pus burrowed extensively into the thorax, although all of the vessels of the neck remained intact. These cases suggest that the family physician call in a throat specialist for every case of acute angina the moment pus develops in the peritonsillar space or side of the neck, and likewise upon the development of chills and permanent temperature Very little is said of bacteriology, but the author regards the blood count as of value, especially displacement to the left—*Deutsche medizinische Wochenschrift,* May 10, 1929

Nonagenarians—Dr Ch Widmer of Lucerne, has for the past twenty years collected data on this subject and now has notes of 97 men and women who had passed the ninety year mark While the material is small compared with that controlled in Humphrey's work on Old Age it is of considerable interest so far as Switzerland is concerned Nonagenarians are exceptional people from the biological standpoint The subdivision by sex is 56 women and 41 men, which appears to indicate a ratio of longevity of 4 to 3 in favor of women The great majority are from agricultural stock The first characteristic isolated by the author is an excess of ectodermic structure—of hair and pigment They do not show their age which is masked under a taut, lean, and dry exterior This physical makeup was present without exception There were no invalids among the lot, no bedridden, no blind, deaf, or lame One will find plenty of these defects among the sexagenarians, but the nonagenarians have become immune Death is quite a different thing in these two periods of life or extremes of old age At the time of writing 69 of the 97 are dead but not from cancer, not from infections, not from gangrene or apoplexy Nevertheless these peoples have not escaped gout or rheumatism although they have outlived those affections, while a majority of the men have had prostatic symptoms The author was astonished to note that none of the men had been a smoker, and every man had been married Celibacy, was of no such disadvantage to the women, for more than half were unmarried Not one of the 97 had been a first born or an only child The author points out that light reading and card playing were unknown in their circles, mostly they complained of the hardness of their lot, but not of ailments and not of the future. The author makes no reference to alcohol although the Swiss have the reputation of being home brewers and distillers Not one had ever submitted to a surgical operation or been under an anesthetic—*Munchener medizinische Wochenschrift,* May 17, 1929

Grippal Pseudoappendicitis—W Wachsmuth mentions the cumulative occurrence of appendicitis in certain epidemics of influenza, in which, however, as the cases were chiefly benign there was always a doubt as to the diagnosis If not true appendicitis, how explain the symptoms? Disregarding the literature and the experience of previous epidemics the author prefers to discuss a series of 11 cases of appendicitis, or apparent appendicitis, seen by him in the past two months After giving brief histories he sums up as follows Every case first presented symptoms of a general infection—depression, pains in the limbs and loins, etc with spontaneous pain in the appendix region Five patients vomited While the abdominal symptoms dominated the picture and led to the diagnosis of appendicitis, the usual evidences of grippe—sore throat, tracheitis, or bronchitis—were noted at the time or somewhat later There was tenderness on pressure in the appendix region, although but one case showed an abdominal defense After a few days the abdominal symptoms receded and the picture of grippe asserted itself Only one case came to operation and here no appendicitis was found, but instead a mild inflammation of the cecum In reviewing these cases at length the author is not satisfied to regard them as appendicitis The symptoms lasted but 2 or 3 days as a rule and all of them vanished completely and permanently There was no history of any previous episode suggesting a prior attack Leucocytosis was present in but four cases Despite the great tenderness of the right hypochondrium muscular rigidity had been as good as absent The author seems unaware of the fact that spontaneous pain in the right hypogastrium seldom or never occurs early in appendicitis and that pain is referred rather to the middle line and to the epigastrium or umbilical region The symptom stands in no relationship to intestinal influenza, which as a

LEGAL

By Lloyd Paul Stryker, Esq
Counsel Medical Society of the State of New York

PUBLIC OPINION AND JURY DUTY

"You never can tell what a jury will do," or to put it in the language of an old practitioner in the Court of General Sessions of New York City, "There are two things about which you never can tell, whether it will be a boy or a girl, and what a jury will do" How often have we heard expressions of similar character in court and out from lawyers and litigants alike

Your counsel came to the Bar a firm believer in the jury system A careful study of the history of the jury system in relation to the life of the peoples in the countries where the jury system obtains, convinced him that despite its human imperfections, it nevertheless was the best means yet devised for the settling of disputes between man and man and the determination of the guilt or innocence of a person charged with a crime Twenty years of experience first as an Assistant District Attorney and later in the trial of civil cases has strengthened and confirmed that view To be sure there are times when a jury's verdict represents a miscarriage of justice, and yet it is remarkable how time and again twelve men, drawn from all walks of life, will sift and analyze contradictory testimony and reach a verdict that represents a triumph of truth and justice.

Your counsel has discussed the subject many times with prominent members of the Bar and Bench, and in nearly every instance has found them to be staunch defenders of the jury system

We have not sufficiently stressed the importance of jurors in the administration of justice We have not made them feel as we should, that they are just as important to the proper functioning of the courts as the judge on the bench We have not sufficiently considered their welfare Perhaps that is one reason that accounts for the large percentage of men, at least in the large cities, who seek to avoid jury duty Jurors are entitled to and should receive every courtesy and consideration, not only from the judge before whom they serve, but from lawyers, court clerks and court attaches with whom the jurors must come in contact during their term of service To one who realizes the vital part that juries play in the administration of justice, it is heartening to note that public conscience and public opinion have in recent years been aroused to the necessity of improving and strengthening the jury system

The judges of our courts are continually stressing the necessity of according the jurors every courtesy, and through cooperation with the various court clerks, they devised a system which already is making for the greater convenience of men who are called to jury duty Only recently in the City of New York a spacious room with telephonic and stenographic service, has been set apart exclusively for jurors Individual jurors with whom your counsel has spoken, have expressed delight at this evidence of consideration for their welfare Courtesy begets courtesy, and when jurors feel that their welfare is being taken into consideration by those who are in charge of running our courts, they in turn feel that they are really a part of the court and are actuated by a strong desire to perform well and truly their duties as jurors

Just a few weeks ago the presiding justice of one of our courts called before him the clerks and court attaches and told them that both he and they were servants of the jurors and that they must treat men who come to serve on juries with every courtesy, kindness and consideration

The Rotary Club of New York has formed a "Legion of Volunteer Jurors" This is part of a campaign undertaken by the Rotary Club in connection with the Association of Grand Jurors of New York County to impress upon the community that jury duty is a badge of honor, and that the man who shirks jury duty is in the same category as one who in times of war, though physically able, refuses to serve his country when called upon to do so These bodies are doing a noble work and they deserve the cooperation and assistance of every true citizen of this state They are seeking to bring home to the public mind and the public conscience the principle enunciated by Judge Merrick in the case of U S against Nardello, when he said "It will not do to say that one shall have of a community all that he can get out of the community and on the other hand shall not return to the community some corresponding obligation of citizenship"

Further evidence of an awakened public conscience and public interest in the subject of better juries, is found in a bill introduced in the legislature at its last session This bill sought to abolish all exemptions from jury service The bill failed of passage, probably for the reason that it was too sweeping in character There is no doubt that too many classes are now exempt from jury duty, and the abolishment of some of

tacked by this malady are about one year of age The author has had one fatal case in his own practice, but two other children were saved, probably by the use of strophanthin Two other cases of rapidly fatal illness are given in detail Although in neither was autopsy obtained the author has little doubt that death was due to the bulbar form of infantile paralysis, in fact the diagnosis was made with little trouble through the peculiar bulbar syndrome and by exclusion It was only required to exclude laryngeal stenosis, which was readily done The author insists on the importance of the neurological examination in these cases and on excluding as far as possible such a vague term as thymic death The possibility of acute cardiac failure from myocarditis should also be borne in mind—*Deutsche medizinische Wochenschrift,* May 24, 1929

The Mouth as an Autobiography—F W Broderick holds that too much emphasis has been placed on infection as a cause of dental disease to the neglect of the underlying cause of susceptibility to infection He contends that in the mouth we have a document demonstrating not only past errors of metabolism in the presence of the stigmata of dental caries and of pyorrhea, but also suggesting the probable condition of the patient in the future by showing the diathesis or susceptibility to disease to which he is liable The reaction of the saliva demonstrates conclusively the state of the acid base equilibrium of the blood, alterations in which reflect the general metabolism of the body consequent upon functional disturbance of the endocrine autonomic system, on which depends the individual's susceptibility to disease Cannon has shown that the emotion of fear, through the stimulation of the adrenal glands, prepares the animal for the exertion of fight or flight Worry and anxiety are the civilized equivalent of fear, and in these conditions the same physiological reactions occur, notwithstanding the fact that, owing to civilized conditions, they cannot be followed by the exertions of attack or defense Hence there results a maladaptation to circumstances The result is overaction of the adrenal glands or their exhaustion, with the consequent effects upon the autonomic system and metabolic derangement These conditions can be recognized by a study of the mouth and oral secretions, the effect, for instance, of a constant increase in alkali absorption will show itself in a tendency to alkalosis and the production of pyorrhea, while an increase in acidity will tend to acidosis and dental caries If the reaction of the saliva demonstrates conclusively the state of the acid-base equilibrium of the blood, then in an estimation of this reaction, carefully considered in relation to all the circumstances of the case, we have a method of diagnosis of greater importance even than that of an examination of the urine and the blood, in that these latter demonstrate only disease conditions, whereas the saliva gives evidence of change before the general pathological upsets have reached that stage The work of an intelligent dentist should not consist entirely in repairing, removing, or replacing damaged teeth, but through the study of mouth conditions he should become a helpful colleague of the medical practitioner—*The Practitioner,* June, 1929, cxxii, 6

The House Mouse as an Etiological Factor in Pneumococcus and Coli Infections—E Palier states that since the labors of Fränkel it is accepted that his pneumococcus is the pathogenic factor in fibrinous pneumonia It is described as a lanceolate diplococcus but the writer regards it as highly polymorphous, and when passed through mice the young cultures may show coccobacillary, streptococcal, and staphylococcal forms Both old and recent authors speak of such transformations The diplococcus is found in the mouths of a majority of healthy individuals but its virulence is greatly attenuated Virulent cultures lose their virulence in a few hours, and man and the rat are normally somewhat refractory to the germ, but after successive passage through mice it will kill rats It has always been a mystery how this germ is able to acquire virulence to mankind—how the harmless organism of the mouth can have its virulence so augmented We may guess that the exposure that often precedes pneumonia may be such a factor, but the disease occurs also in hot countries, while in the polar regions man seems immune In the interior of Iceland the disease is all but unknown, although it may develop in the seaports, soldiers' barracks, etc We may imagine that the domestic mouse is a factor, that infection may be spread by fleas or that the excreta of the animals may infect the air Dead mice contain many virulent organisms Not only pneumonia, but appendicitis, puerperal infection, etc may originate in this manner The rat is less of a menace, but is susceptible to coli infection and may be a factor in the transmission of the same These rodents may perhaps be infected from human sputum and thus become new foci of infection Houses with cats seem to show some immunity to pneumonia over houses without cats, according to figures quoted from Béguins of Antwerp—*Bulletin de l'Academie de Médecine,* May 7, 1929

defendant operated without consent, and furthermore performed the operation in such a negligent manner as to puncture certain of the plaintiff wife's internal organs

When the case appeared on the calendar, plaintiff's attorney did not even answer it and it was marked off the calendar and subsequently a motion was made by us to dismiss the case for lack of prosecution, which motion was granted, thus terminating the action in the doctor's favor

OBSTETRICS—CLAIMED WRONG DIAGNOSIS

In this case, an action was brought by the husband and wife against the doctor, the charge being that he diagnosed the condition from which the plaintiff wife was suffering as a tumor, whereas in truth and in fact she was pregnant, and that relying upon his advice, she submitted herself to an operation It was further alleged that she never had a tumor, and that the operation was unnecessary and was done through ignorance on the part of the defendant

The plaintiff wife was referred to the defendant doctor for examination and treatment by another physician The defendant examined her, and found that she was pregnant about five months and also that she was suffering from a uterine tumor He ordered that she be sent to the hospital, and subsequently under a general anesthesia he opened her abdomen and found a subserous fibroid tumor in the interior wall of the uterus He removed the tumor The patient remained in the hospital about three weeks and had an uneventful recovery She was discharged from the hospital by the defendant, and he never saw her again

After the action had been commenced, the plaintiffs did not take any steps to prosecute the action, and finally on our motion the complaint was dismissed, thus terminating the action in the doctor's favor

OBSTETRICS—CLAIMED BREAST ABSCESS

In this case, a woman called at the defendant's office, and after examination he pronounced her to be about five months pregnant She arranged with the physician to handle her case during confinement and delivery The doctor saw her at intervals of about a month apart after her first visit.

At term, the doctor delivered her of a normal female child The delivery was in all respects a normal one About four or five hours after the delivery, the woman had three or four convulsions which the defendant diagnosed as eclamptic, but she recovered from them and was getting along very well

About two weeks after delivery, she complained of sore nipples, and the doctor upon examination found that they were macerated due to nursing the child On the following day, the woman complained of pain in the right breast The doctor put an icecap on the spot, but as the woman was going home the next afternoon, she said she would have the condition attended to by another physician The doctor never saw her again

She and her husband subsequently brought suit, charging that the defendant conducted himself in and about the delivery of the child and in taking care of the plaintiff wife subsequent to delivery in such a negligent manner that the right breast of the plaintiff wife became infected After the filing of the suit, however, the plaintiffs discontinued the action

these exemptions would make available men whose intellectual and moral qualifications would do much to strengthen the tone of the jury panels in our courts But there are classes of men that are justly entitled to jury exemption Reasonable men, we think, will agree that physicians should not be compelled to serve on juries They give liberally of their time and talents in the interests of suffering humanity In the practice of their profession they are returning to the community their full measure of obligation for their rights as citizens But the medical profession can and should aid and assist in the campaign for better juries Doctors are regarded and rightly so, as amongst the leaders of their community They have the respect, the admiration and the affection of their fellow citizens By lending the weight of their influence to the ideas here expressed, they will be doing their share to the furtherance of a system which is the greatest safeguard of the peace, happiness and prosperity of the citizens of this state

GONORRHEAL PYOSALPINX—CLAIMED OPERATION WITHOUT CONSENT AND NEGLIGENCE IN THE PERFORMANCE THEREOF

In this case the doctor was called in to see a young married woman When he arrived at her home he found her in bed with a temperature of 104° She gave a history of having been sick with a high fever for five days and her chief complaint was pain in the right lower quadrant, and that she had been unable to sleep, that her trouble began with a vaginal discharge, frequency of urination, a burning sensation in passing water and a continual dull pain in the lower part of the abdomen A vaginal examination disclosed a white purulent discharge (microscopically containing gonococcus of Neisser) The uterus had lost its natural mobility At the right side of the cervix there was a hard mass that pushed the cervix toward the left, the whole vaginal vault was very hard, fluctuation was entirely absent An examination of the abdomen disclosed it very distended, but there was no special localization of pain or any mass felt The doctor spoke with the woman's husband and discovered that he had had a gonorrheal infection which had not been properly treated and to that fact the defendant traced the source of the wife's infection The doctor made a diagnosis of gonorrheal pyosalpinx The doctor explained the expectant treatment, ice bags to the abdomen were ordered as well as vaginal douches of one-half per cent of lysol, and morphine was given for the pain, an enema was also ordered and the patient was instructed to remain in absolute rest He instructed the husband and wife to abstain from sexual intercourse

The next day, as the abscess was pointing toward the vagina, the defendant informed the husband of the necessity of an operation The woman was taken to a hospital and a consultant who was called in confirmed the defendant's diagnosis The patient's written consent was obtained for the operation Under an ether anaesthesia the doctor introduced a needle and syringe through the posterior right vaginal fornix A large amount of pus was found and a large opening made by blunt dissection The pus was drained, irrigation used and the cavity packed with iodoform gauze and a vaginal pad applied After the evacuation of the pus the patient improved immediately, the temperature dropped the next day almost to normal.

About a month after the patient left the hospital she called at the doctor's office complaining of feeling generally ill The doctor found that she had a temperature of 103° and immediately sent her home While talking to her he found that his instructions with respect to abstaining from sexual intercourse had not been followed, and also that she had disobeyed other instructions he had given her The next day he called at her home and found her temperature was up to 104° She was in considerable pain A vaginal examination disclosed a stony hardness of the vaginal vault and the position of the fundus could not be located, as on both sides of the cervix and especially toward the left, there were hard resistent bodies A bimanual examination showed only that the peritoneal floor of the pelvic cavity was dense and resistant The mobility of the uterus was very limited The doctor advised that the patient go to a hospital, but both she and her husband objected A consultant was called in who, after examination, agreed with the treatment rendered by the defendant and recommended that she be sent to a hospital, stating that good drainage through the previous point of evacuation might relieve the condition as sometimes new abscesses of the pelvics are found to communicate with the old ones Both the patient and her husband refused the doctor's advice with respect to sending the wife to a hospital, and the husband suggested another consultation This was done and the second consulting physician fully agreed with the diagnosis and treatment which had been rendered to the wife by the defendant, and expressed the opinion that gonorrheal pyosalpinx usually became chronic and is characterized by frequent exacerbations The patient finally went to a hospital under the care of another physician and the defendant did not see the case again

Subsequently both husband and wife began this action against the defendant charging that the

NEWS NOTES

DISTRICT BRANCH MEETINGS

Seven of the eight District Branches have selected the times and places for their annual meetings as shown by the following table —

Fourth District Branch, Saratoga Springs, September 19-20

Third District Branch, Kingston, September 21st

Sixth District, Cortland, September 25th

Seventh District Branch, Clifton Springs, September 26th

Eighth District Branch, Buffalo, October 3rd

Fifth District Branch, Watertown, October 17th

First District Branch, Yonkers October 25th

GRADUATE COURSES

Definite arrangements have been made for post graduate courses in the following counties for the subjects listed

Tioga	Traumatic Surgery
Steuben	Internal Medicine
Washington	Internal Medicine
Sullivan	Internal Medicine
Wayne	Surgery
Ontario	Surgery
Monroe	Heart Disease
Genesee	Heart Disease

In addition we have under consideration plans for courses in these counties Clinton, Columbia, Madison, Schoharie and Otsego Several other counties will probably make requests very shortly

As was done last year, Livingston County will probably combine with Monroe County, Wyoming and Orleans Counties will join with Genesee County, while Seneca County will probably combine with Ontario County for its course

It is imperative for counties desiring a course during the coming year to get in touch with us early

A course on Tuberculosis in Rockland County has been completed This course was sponsored jointly by the State Department of Health and the State Medical Society

THOMAS P FARMER

THE NEW DIRECTORY

Copy for the Annual Medical Directory of New York, New Jersey and Connecticut will go to the printer in August, and the reading of the proof should be completed by the end of September

Each year there are a number of physicians who delay sending their new addresses, telephone numbers, etc until all the proofs have been read and the pages made up It is therefore very important if there are any changes in your record for the Medical Directory that you send them at once to the Medical Society of the State of New York 2 East 103rd Street, New York

PRESCRIPTION FOR EPIDERMOPHYTOSIS

Dr E W Ruggles of Rochester has called our attention to an omission in the prescription printed on page 742 of the July fifteenth JOURNAL in connection with his article on Some Phases of Epidermophytosis" The prescription should have read

Zinci Oxidi	drams 1½
Petrolati flavi	drams 2
Ung picis liquidi	drams 3
Ung aqua rosae	drams 2½
M et adde Phenol 95 per cent	minims 15

LONDON LETTER

KING'S COLLEGE, LONDON, CENTENARY

The centenary of King's College, London, which is being celebrated this week, is an event which evokes memories of a long since dead controversy At the beginning of the 19th Century Oxford and Cambridge were the only Universities in England, and the range of studies at each was very narrow, for modern languages and natural or experimental science were not included in the curriculum But probably the most potent cause of dissatisfaction lay in the religious qualifications of undergraduates, for at Oxford the candidates were obliged to subscribe to the Thirty-Nine Articles and at Cambridge the candidate had to make a declaration that he was a member of the Church of England before he could take his degree Thus were excluded the sons of many distinguished families among Roman Catholics and Nonconformists in general, of whom the Quakers alone represented no inconsiderable part of the wealth and intellect of the middle classes Thomas Campbell, the poet, soon after to be made Lord Rector of Glasgow University, in a letter to the "Times" on February 9th, 1825, was the first to propose a practical solution by the foundation of a College in which the most advanced education should be accessible to all without religious tests or distinctions The University of London, University College, was opened in 1828 and among the members of its first Council were Isaac Lyon Goldsmid (the first Jew to receive a Baronetcy), the eleventh Duke of Norfolk (representing the oldest Roman Catholic member of the Peerage), Zackary Macaulay, who did so much to abolish slavery and who was the father of Lord Macaulay, and James Mill, the father of John Stuart Mill After much discussion among those representing the various religions affected, it was decided to restrict the teaching exclusively to secular subjects, and to leave religious training to parents and guardians. This gave rise to much opposition among those who thought that religious teaching should form a part of all systems of education, and King's College was founded in 1829 as a College "in which instruction in the doctrines of Christianity as taught by the Church of England should be forever combined with other branches of useful information" It was not until 1836 that King's College was formally included in the University of London The old animosities are long dead and for many years University College and King's College have worked amicably side by side to make the University of London the great power in education that it has become

DIETETICS

Among the recreations of medical men is that pleasant practice—the "busman's holiday," as it used to be called—of watching others work This agreeable task took me to Sheffield recently, and after an afternoon spent in the operating theatres of the Royal Infirmary, we were transported to the Field Farm where Dr Mellanby is doing experimental work on Dietetics He tried the effect of strawberries and cream upon us, and then showed us the results of many investigations on vitamin feeding and deprivation Dr Mellanby has two important investigations on hand He is testing the effect of diet on the growth and metastases in tar cancer in mice, but it is too early to say more than that it seems that the better the feeding the more rapid the cancer growth But his other investigation has passed the stage of experiment and has been used in treatment By a series of tests Dr Mellanby came to the conclusion that absence of Vitamin A rendered the body susceptible to septic invasions, and he treated several cases of puerperal fever, in whose blood the streptococcus haemolyticus had been isolated, with radiostoleum, a combination of Vitamins A and D The result was highly satisfactory and the treatment has now been extended to other cases I saw a man making a good recovery from an aggravated condition of diffuse peritonitis, to whom radiostoleum had been given, and there seems justification for further work with the remedy both in prophylaxis and treatment

J W CARSON

plex. The idea that New York is 'going native' is a delight to humorists However, we are sure caution will be used by Dr Brown's assistant Most parents may prefer to have an examination by a family doctor before any toxin-antitoxin is administered to their offspring"

REFRIGERATING GASES

The gas used in household refrigerators has come within the sphere of public health and industrial medicine. The New York *Herald-Tribune* of July 17th, describes three fatalities as follows

"Three members of a family, found dead in bed late today in the Richmond Apartment Hotel, are believed to have been killed by the inhalation of methyl chloride fumes escaping from the mechanical refrigerator in their apartment

"This opinion was advanced by Coroner Herman N Bundesen after an examination of the dead and premises and by Health Commissioner Arnold Kegel upon receiving reports from his investigators

"The Painters, according to Dr Bundesen, apparently had felt ill in the evening and retired There was evidence that they were conscious for a time, though not aware of the cause of their illness, as methyl chloride has no distinctive odor

"Morris Schmukler, manager of the building, which contains seventy apartments, all refrigerated from a multiple system operated from the basement, told the investigators that he had heard the leaking noise last night After a search failed to reveal any escaping gas he returned to bed, he said

"Food in the refrigerator cabinet was frozen, indicating, according to Dr Kegel, that the leak had been in the ice box Though three windows of the one-room kitchenette apartment were opened, the large amount of gas in the multiple system which was leaking into the small apartment was sufficient to cause the deaths"

A number of kinds of gas are used in household refrigerating systems, including ethyl chloride and sulphur dioxide There should be information available to medical men regarding the gases and their effects on the human body Most physicians know very little about refrigerating gases and the manner of operation of ice boxes

BARBERS PRACTISING MEDICINE

There is a reversion to ancient customs recorded in several newspapers in the story of a barber charging an unsophisticated man from Boston a large sum for facial treatments when the customer wanted only a hair cut The New York *Sun* of July 10th, made a humorous story about a barber who discoursed to his customer in a variety of subjects in the course of which he remarked casually, "you have a blackhead on the end of your nose, shall I take it off for you?" and the Boston man said "yes," when he meant that he would have a shave—or at least that was what he told the court after the barber had charged him $7 65, the seven dollars being for violet light treatment, only the *Sun* happened to spell it VIOLENT The judge asked the barber if he had a list of prices posted in his shop, and when one was produced the judge said "If a man took every kind of treatment listed here, the bill would be only $6 50 Give the customer back his seven dollars"

The Brooklyn *Eagle* of July 15th, took a medical point of view of what was evidently the same case, for it carried a seven line item reading

"There ought to be no trouble bringing to time the barber in Manhattan who charged a Boston visitor $7 65 for a shave and a 'facial treatment for sunburn' Clearly the tonsorial artist was practicing medicine without a license and the Medical Society sleuths should see to it that he does not escape."

We wonder if many barbers are giving ultra-violet light treatments It would not be strange if they were, since ultra-violet lamps for household use are advertised with the apparent sanction of some medical societies

The Brooklyn *Eagle* is wrong if it expects the representatives of medical societies to do sleuthing work for detecting violators of the medical practice act That law taxes every registered physician two dollars a year for the purpose of carrying out the provisions of the act The money goes to the representatives of the State Department of Education and the Attorney General to be applied to detective work and the prosecution of illegal practitioners

THE DAILY PRESS

THERAPEUTIC VACATIONS

AND SOME PEOPLE THINK HE ISN'T CATCHING ANYTHING

Cartoon by Brown in the New York Herald Tribune, July 30 1929

This cartoon expresses a scientific truth far better than words can do When a person goes on a vacation, what does he get? The word "vacation" comes from the same root as vacuum,— emptiness,— and therefore receptiveness The therapeutic value of a vacation depends on an emptiness of mind, for no one can put new ideas into any part of the mind which is already overflowing with habitual worries It is hard to tear ourselves away from our old associations that grind the highways of our thoughts into ruts along which our minds travel back and forth in futile unrest The fundamental principle of a vacation is that we shall jolt ourselves out of our habitual ruts and into unfamiliar scenes where our minds are vacant, and we are free to follow the whims and fancies which are survivals of our younger days

When we take a real vacation, we become small boys released from the stiff-backed chairs of the parlor and company, and turned loose out of doors where we may do whatever we wish,— and what we most desire is to experience the same pleasures which delighted us as small boys Can anything be more ecstatic and satisfying than the expression on the face of the man in the cartoon who has resurrected his childhood experiences and expectations and is satisfying the subconscious desires that have been repressed during years of drudgery? That man is taking potent doses of a therapeutic vacation

HEALTHMOBILES

The New York City newspapers have discovered that the "Healthmobile" is a good subject for news items, and yet the idea was put to use some fifteen years ago by the New York State Department of Health when it used an automobile to transport the materials for child welfare clinics, and to provide electricity for stereopticons and moving picture projectors The city uses the "Healthmobile" as an attraction rather than a means of transportation

The tendency of most health teaching, especially to children, is to make an appeal to strength or beauty, or some other desirable quality, rather than health itself A child, for example, is urged to take care of his body in order to become a Charles Lindbergh The Brooklyn *Eagle* of July 15th, in its editorial columns, explains this attitude as follows

"Each 'Healthmobile' will carry a clown and an assortment of toys and toy balloons Dr Edward Fisher Brown, director of the diphtheria clinic, explains

" 'We are taking a page from the history of the old Indian medicine doctors and putting it to use in the field of modern health work * * * The children's attention will be distracted from the doctor's activities by the toys and antics of the clowns'

"Unquestionably the motive behind this sort of thing is a fine one. Veteran missionaries of long service in India, in China, in Central Africa will nevertheless smile gently Such methods have been used often in lands where every prospect pleases and only man is vile The heathen in his blindness yields to the universal toy com-

BOOK REVIEWS

RÖNTGENOLOGY The Borderlands of the Normal and Early Pathological in the Skiagram By ALBAN KÖHLER, Prof Dr med. Rendered into English from the Fifth German Edition by ARTHUR TRUMBULL M.A., B Sc., M B Octavo of 556 pages illustrated New York, William Wood & Company, 1928 Cloth, $14 00

This is an English translation of the Fifth German Edition consisting of five hundred and forty-two pages and index with three hundred and twenty-four illustrations.

This book of Dr Köhler's deals with anatomy physiology and pathology as shown by roentgen examination The anatomical study is of special value Almost half the work is devoted to the osseous structures including a very full description of abnormalities of development in contradistinction to pathological states A careful study of these pages will soon disclose the fact that many of the conditions which are too often considered pathological—traumatic, in medical-legal cases—are nothing more than developmental irregularities or normal variations The importance of the presentation of this portion of the subject cannot be too strongly stressed and it should be familiar to every roentgenologist

The remainder of the work on general roentgenology is complete in practically every detail Numerous illustrative cases are cited and the introduction of the clinical aspect of these cases adds materially to the interest There are numerous expressions of opinion on certain subjects to which your reviewer cannot subscribe but that is purely a personal issue. The statement that epiphyseal separation is rare, the denial of atrophy of disuse of bone and the assertion that productive myositis ossificans is bilateral, are statements which are certainly open to criticism.

An important feature which is usually overlooked in most books on roentgenology but one that is covered here, is the careful consideration of the study of the soft tissues of the extremities

The illustrations are good and the line drawings are especially to be commended but they could be made of more value if the author had placed the descriptive captions under each illustration instead of necessitating a search of the text for the description

This book of Dr Köhler's is so interesting and instructive that one regrets that certain portions had not been considered in further detail thus making it a monumental work instead of merely the best which has yet been produced in English. C. E

PARTNERSHIPS COMBINATIONS AND ANTAGONISMS IN DISEASE. By EDWARD C B IBOTSON M D B S Octavo of 348 pages Philadelphia, F A Davis Company, 1929 Cloth $3 50

This book presents new aspects of our ideas concerning disease Many questions are presented in the text and many arise in the mind of the reviewer because of the facts and suggestions given by the author Some new points of view are given for consideration and thought. The question of the influence of ancestry on the health of the individual is discussed "The whole doctrine of diatheses which had been overshadowed by the new science of bacteriology has received new life from serum therapy and from endocrinology" "As an individual may have one or more deficiencies or excesses so he may have one or more diatheses As inheritance plays so great a part in diatheses the excess in one parent may tend to neutralize the deficiency of another" The author has presented much material for consideration, and this book will well repay the careful study necessary to get the author's point of view

HENRY M MOSES

A HANDBOOK FOR THE DIABETIC By ALBERT H ROWE B S, M S, M D 12mo of 129 pages New York Oxford University Press, 1928 Cloth, $2.50 (Oxford Publication)

Doctor Rowe has added a new member to the family of manuals for the diabetic. His manual does not differ greatly from the others—indeed they all seem to be cut pretty much from the same pattern.

Doctor Rowe aims to instruct the diabetic, and he has addressed his manual to patients and not to doctors. He has given all the facts but his manner of presenting his material is rather one of generalization than of particulars, and his style is not particularly stimulating or inspiring

He has included in his book, along with the required tables a very good list of recipes for diabetic diets—some of which are new and welcome. For variety is difficult to obtain in the diet of the diabetic and more difficult in the matter of the diabetic manuals

This one is neither remarkably good nor bad It is a good, steady statement of the facts over the heads of many diabetics and not sufficiently striking for the majority

L. C JOHNSON

THE FUEL OF LIFE. Experimental Studies in Normal and Diabetic Animals By JOHN JAMES RICKARD MACLEOD, M B LL.D Octavo of 147 pages Princeton, Princeton University Press, 1928. Cloth, $2.50

The subject matter of this book comprises four lectures delivered at Princeton University and "reviews" says the author, "what appears to me to be of importance in our present knowledge, concerning the preparation of the food materials for combustion in the animal organism, and deals more especially with the question as to whether fats, as well as proteins, form carbohydrates before being used as fuel"

He is thus interested in the intermediary substances of carbohydrate metabolism, and a consideration of these details is so involved, the evidence of the various investigators so varied that no one is better fitted by nature' in experience to give as complete and fair a summary as Doctor Macleod His ability to see clearly, to say much in few words and to keep his material alive and moving no matter how heavy or difficult it may be, is such that it always commands admiration and attests the hand of the Master"

The Fuel of Life' is not for one who is out for light reading but for him who seeks light in the matter of the oxidative processes which have to do with life. and is a masterly summary of the acquired knowledge to date—with a critical review on the part of the author as well as a clear statement of his own beliefs, doubts and in certain instances, inability to fix upon any one conclusion.

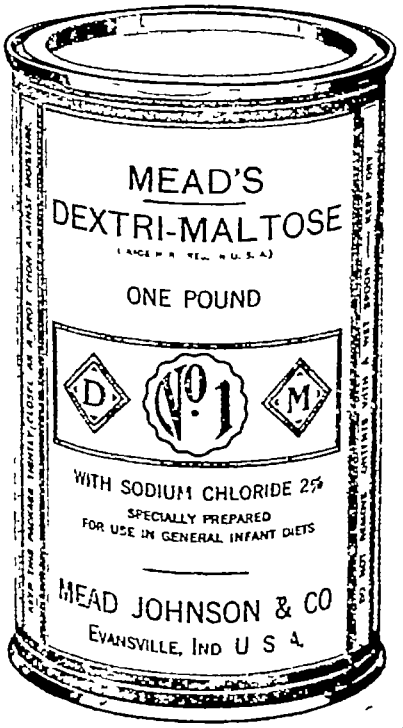
COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION Edited by Mrs M H MELLISH, and others Volume XX, 1928 Octavo of 1197 pages, illustrated Philadelphia and London, W B Saunders Company, 1929 Cloth, $13 00

Sound weight and muscle on MEAD'S DEXTRI-MALTOSE

MEAD'S Dextri-Maltose, cow's milk and water can, with but few exceptions, be relied upon for good results in artificial feeding cases



The addition of Dextri-Maltose makes up the carbohydrate deficiency in the cow's milk It is easily assimilated—well tolerated

Gains in weight are usually normal, presenting a healthy clinical picture—sound musculature—good color

There is a minimum of nutritional disturbances of a fermentative nature due to the greater assimilation limits of Dextri-Maltose over either lactose or sucrose

Dextri-Maltose No 1 is indicated for normal infants, while the No 3 with 3% addition of potassium bicarbonate, is the clinical choice if calcium constipation is present

These observations are made from the results obtained in hospitals, in clinics and from many physicians in private practice

THE MEAD POLICY

Mead's infant diet materials are advertised only to physicians No feeding directions accompany trade packages Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant Literature furnished only to physicians

OUR NEIGHBORS

MEDICAL EXTENSION LECTURES IN WASHINGTON

The July issue of *Northwest Medicine* describes a series of medical lectures for physicians as follows

"There is no medical department in connection with the University of Washington During the last twelve years, however, the extension service of the University has sponsored a graduate medical course of lectures in Seattle, when many distinguished leaders of the medical profession have appeared before audiences composed of physicians from all parts of the state General medicine and surgery, together with well known specialties in each of these branches, have been covered by leaders in their various lines of practice This year the committee in charge has decided to vary the program of subjects which have commonly been presented in past years, and have arranged for series of lectures which it is believed will prove profitable to all who take advantage of them

"Dr John C Coulter, of Chicago, professor of physical therapy at Northwestern Medical College, will cover all phases of the practical application of this group of remedial agencies

"Dr Richard H Jaffe will present the most recent information resulting from pathologic work in European laboratories Dr Victor C Myers, professor of biochemistry, Western Reserve University, Cleveland, Ohio, will discuss the applications of chemistry to medicine Dr Jennings C Litzenberg will present the subject of obstetrics and gynecology"

EDUCATIONAL COMMITTEE OF THE ILLINOIS MEDICAL SOCIETY

The Educational Committee of the Illinois Medical Society in its report to the annual meeting told of an immense amount of work done

The following quotations are taken from the July issue of the *Illinois Medical Journal*

"There has been a growing interest on the part of the public in the matter of health and healing This interest is evidenced in the great amount of advertising promoting various products in their relation to health One needs only to scan the advertising sections of newspapers and magazines and the show cards in public vehicles to be convinced that the word 'health' is being used today more than any other one word How is the public to determine what portion of this health propaganda is good or bad? That information can best be secured through sources such as state medical associations and their component societies

"The Illinois State Medical Society in establishing an educational program for the state must have had in mind that, 'It is just as much a deception of the public to have something good for them and not tell them as it is to have something bad and tell them it is good.'

"An important part of its work has been the cooperation given certain lay groups of the state Your Committee has been represented at the organization meetings of the Elks Foundation for Crippled Children and satisfactory plans have been set up for crippled children's clinics The Foundation has definitely stated that these clinics will be held only in counties where the medical society wishes, and that no patients will be admitted to these clinics unless accompanied by the family physician or with his consent

"The Chicago Woman's Club has been especially interested in promoting an educational campaign concerning cancer The Committee has been represented at the conferences of the Club and when a definite educational program is launched, the Educational Committee will take an active part in promoting intelligent information about cancer

"The Committee has been represented on the Advisory Council of the Child Hygiene Division of the State Department of Health The Council has approved a plan for work in several counties of the state which will require the cooperation of the Medical Society, Dental Society, and certain lay groups Such a plan of procedure should make for a much better understanding, on the part of community groups, relative to certain health problems which may be studied

"The Home Bureau organization of Illinois has been given more or less assistance In one county, health talks were given by physicians before all of the home units The Home Advisor wrote 'Reports on talks by the doctors are that they gave the women material which will be most valuable to them I think the plan a splendid one and hope that you will feel that results will justify the use of a similar plan in other counties'

(*Continued from page* 1036)

"In order to reach many groups of people health education has been promoted through various channels The health column prepared by the Committee and released to newspapers for use over the signature of the local medical society has had a definite place in this educational program There has always been some question as to whether or not a press service would be worth while and satisfactory to the medical profession and the public In order to get some idea as to the answer of this question, a letter was sent out to 81 editors and a number of physicians These replies indicated that the service is needed and that the public is interested

"Special publicity has been given by the Committee to some of the more important meetings called by county medical societies These news items give the public an opportunity to know that county medical societies are functioning Many physicians feel that announcements appearing in local papers have been of appreciable value in stimulating interest and better attendance at these meetings

"Educational articles have been sent into communities where epidemics have occurred Articles were released to all newspapers in the state during the influenza epidemic in December Special articles were prepared on health topics emphasized for observance during Health Week All newspapers received these articles for publication over the signature of the Illinois State Medical Society

"One hundred and ninety new educational articles were written and approved by the Committee.

"Ten thousand two hundred and seventy-five press articles were released to Illinois newspapers Many more newspapers would be willing to carry a series of health education articles over the signature of the local county medical society, if physicians would take the responsibility of securing the interest of the editors This health column furnished by the Educational Committee is better than some and as good as many columns for which editors are paying a high price

"The radio, which today represents one of the greatest advertising mediums, has also been used by the Educational Committee Health talks have been given by members of the profession over stations WGN, WLS, WJJD and WHT At the present time WGN and WJJD are being used every week The Committee approves all material which is broadcast. Daily talks were given during the influenza epidemic"

(*Continued from page 1040—adv xiv*)

which he has crusaded during the past year, among them being

"1 Lay dictation and control of medical practice

2 Endowed foundations entering practice of medicine

3 Corporations engaged in medical practice.

"4 Inimical medical legislation.

"5 Political control and interference with medical practice

"6 Unrestricted activities of quacks with general public health

"7 Lay and semi-lay pay clinics for other than the poor

"8 Supersedence of physician by overtrained nurse

"9 Health departments practicing general instead of preventive medicine."

The editor enumerates the following causes for which he is fighting

The causes which the *Journal* is fighting for

"1 Defense of the medical profession from emotional vilification

"2 Protection of the profession from misleading opinions engendered in the public mind through unfair, untruthful, and bombastic newspaper publicity

"3 Restoration of the rank and ranks of the family physician

"4 Realization on the part of both mature doctor, recent graduate and undergraduate student that the general public is demanding increasingly a punctilious service for those comparatively trivial ailments that comprise the bulk of human ailments and that proffer fertile mediums for the increase of charlatanism"

COLORADO'S EXECUTIVE SECRETARY

The Colorado State Medical Society has employed a full-time executive secretary, who however is a layman, a newspaper reporter by profession Concerning his work Colorado Medicine for June says

"The determining factors in the selection of the secretary were educational qualifications, experience in the world, age, moral character, editorial experience, salary required, place of residence.

"Mr Sethman will be ushered into office on the first of June. His duties will be new to him and it will probably take some time for him to adjust himself to the atmosphere of the medical profession and generally to get his bearings The new secretary will begin to familiarize himself with the mechanical, advertising and editorial duties connected with Colorado Medicine, so that

THE ILLINOIS MEDICAL JOURNAL

The report of the editor of the *Illinois Medical Journal,* Dr C J Whalen, given at the annual meeting on May 21 is pessimistic although the editor says that he is optimistic The report in the July issue of the *Illinois Medical Journal* says

"The editor of the *Illinois Medical Journal* makes his annual report with a feeling of optimism held in leash by the knowledge that the twelve months just ending have not seen medical victories snatched from the jaws of defeat, jaws that even yet are closed tightly on the throat of medical progress and security

"The year just past has seen alarming fulfillment of those menaces against which this *Journal* has so faithfully and so honestly crusaded Not even the increased circulation, the finest showing of income returns in the history of the *Journal,* nor the general respect with which the pronouncements of these columns are viewed, can compensate for the solar plexus blows that state medicine and socialistic groups have dealt the basic elements of a just and righteous system of medical economics and of scientific skill

"Not only has it been necessary during the past year for the thinking few to fight the battle of the soporific many against an extension of the Sheppard-Towner Bill, lately appearing legislatively as the Newton Bill, the progenitor of which is occupying a high place in the present cabinet, but the year has delivered as a lusty, sturdy infant the pay clinic, endowed foundations, universities and tax-supported medical schools practicing medicine One proposition of the pauperizing tendency upon the part of misinformed and certainly misguided philanthropists has considered the feasibility of extending a free service or at the most, a very low partial payment system to families with incomes ranging upward as high as $6,000 per annum

"Coupled with the increasing tendency to practice medicine by corporations and through legislation, it is of small satisfaction to the editor of the *Illinois Medical Journal* to see his predictions of the past years so undeviatingly approaching fulfillment Like Cassandra of old, such verification of prophecy is disaster of such magnitude that even in justification of doctrines lies no small savour of satisfaction

"In his intense desire to at all times one hundred per cent safeguard the vital interests of the individual physician, as well as the interests of organized medicine, the editor has had constantly in mind the vitalities to be guarded against as destructive eventualities in public economics and the future of both medicine and of the public health and welfare, and of national stability as the medical profession itself has constructed"

The editor enumerated twenty evils against

by the first of the year at the end of the present editor's term, he will be in a position to take over a great part of the burdensome details of the journal publication

"It is to be remembered that the Society will always have a medical secretary who with the other members of the executive committee will supervise the work of the executive secretary

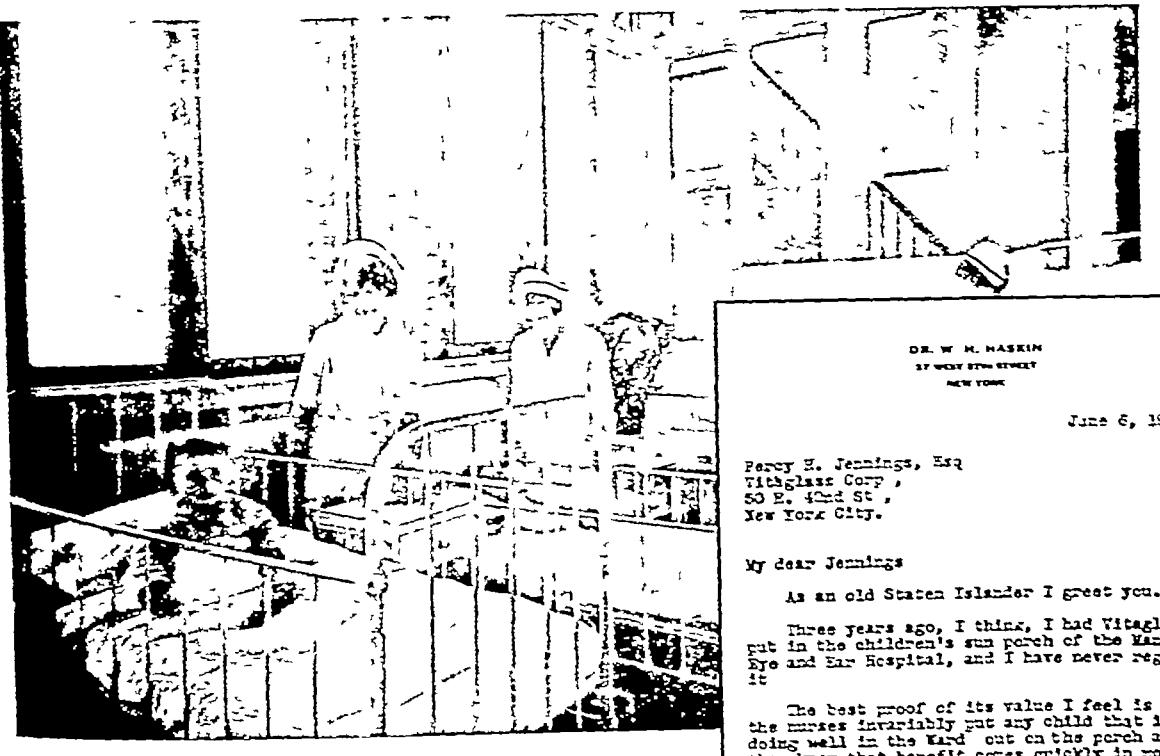
"An office is being fitted up for Mr Seth man in the Metropolitan Building and he will do all his own clerical work, typewriting, etc., until such time as his duties demand the assistance of an office secretary"

MEANING OF "MEXICANS'

Mexico like the United States is a nation composed of many races of various origins To designate a person as a Mexican is as unscientific as to say that an inhabitant of the United States is a "United Statesan"

Dr F P Miranda, of Mexico City explains the meaning of the word "Mexican" in the following letter in the *Journal of the American Medical Association of* July sixth

"As officer in charge of the interchange office of the department of public health in Mexico, I received from the United States several bulletins of the departments of public health of different states and counties In these bulletins I have noted that the term 'Mexican' is used incorrectly as denoting a certain race or color In the interest of uniformity and truth in the basis of classification in vital statistics, I take the liberty to discuss the subject In Mexico there are many white inhabitants with Mexican nationality, chiefly of Spanish origin The rest of the population is composed of pure Indians, mixed Indians and white, negro, mixed negro and white (mulatto) and mixed Indian and negro The word 'Criollo,' or creole, is used to designate the pure Spanish white inhabitants



"Even among the Indians there are different types, and there is great difference between the Aztec and the Maya Indians, not only racially but also in type of civilization

"In the basis of classification of races or color, Mexicans can be classified as Indians, white and negro according to the predominance of race in the individual, otherwise there is no scientific use for such classification

"Perhaps it would be of use to make a distinction between the American Indian and the Mexican Indian, which are also different in race and type of civilization

"The wrong use of the term Mexican is especially observable in California"

Vita*Glass Brings Ailing Children Back to Health at Manhattan Eye and Ear Hospital

DR. W. H. HASKIN
57 WEST 57TH STREET
NEW YORK

June 6, 1929.

Percy H. Jennings, Esq
Vitaglass Corp,
50 E. 42nd St,
New York City.

My dear Jennings

As an old Staten Islander I greet you.

Three years ago, I think, I had Vitaglass put in the children's sun porch of the Manhattan Eye and Ear Hospital, and I have never regretted it

The best proof of its value I feel is that the nurses invariably put any child that is not doing well in the ward out on the porch and they know that benefit comes quickly in most cases.

With best regards and wishes, believe me

Very sincerely,

W H Haskin

The record made by Vita glass in three years of trial on the children s sun porch of the Manhattan Eye and Ear Hospital is told simply and emphatically by Dr W H. Haskin, in the accompanying letter As he says

" The best proof of its value I feel is that the nurses invariably put any child that is not doing well in the ward out on the porch and they know that benefit comes quickly in most cases "

And in more than 350 other hospitals and sanitoria throughout the United States and England Vita glass is achieving similar results, and winning the same enthusiastic approval, for its unfailing service in the overcoming of disease and the fostering of sound health For Vita glass brings to the patient the essence of Nature s healing power —the ultra-violet rays—to which the ordinary window is an impregnable barricade

The power of Vita glass to transmit the vital ultra-violet of natural light is guaranteed permanent.

Vita glass is being marketed primarily as a health prophylaxis, and not as a therapeutic agent; although it is now serving in the latter capacity in numerous well authenticated instances—particularly in the solaria of more than 200 hospitals in England and the United States.

Vita Glass Transmission Constant After Few Weeks' Exposure

Vita glass has been subjected to numerous accelerated weathering tests by the U S Bureau of Standards, by Professor Stockbarger of the Massachusetts Institute of Technology, and by many other physicists These physical or quantitative tests, as well as biological experiments with rats and chickens, have established the fact that the solarization (weathering or seasoning) of Vita glass takes place quickly; and that after a few weeks of actual use its transmission of ultra violet light becomes constant.

VITA GLASS

As Lasting as the Solar System

**VITA is the trade-mark (Reg U S. Pat Office) of and indicates glass and glass ware manufactured for and sold by Vitaglass Corporation, New York City*

SCIENTIFIC SERVICE COMMITTEE OF THE ILLINOIS MEDICAL SOCIETY

One function of a State Medical Society is to assist its component county societies in their educational campaigns for the benefit of the physicians themselves and also of the people generally This function is emphasized by some State Societies to a greater extent than it is in New York State

The annual report of the committees of the Illinois Medical Society printed in the July *Illinois Medical Journal* gives the following description of the unique assistance given to county societies in their programs

"The Scientific Service Committee has functioned chiefly as a Speakers' Bureau during the past twelve months, and has further attempted to stimulate activity in some County Societies that were having difficulty in securing speakers and arranging programs Last September a letter was sent out to all Secretaries asking that they send in the names of physicians in their counties who might be called upon to fill appointments before scientific groups A number of names were added to the list of speakers and at the present time about 300 speakers are listed in Chicago and down state The subjects represented cover the entire field of medicine It is now possible to schedule speakers over the entire state upon any subject requested

"The chief difficulty has been in securing men down state to fill scientific appointments The Committee has felt that this was due to the fact that when requests were made, the men selected did not have their papers ready In some cases those wishing to speak had not given definite enough subjects to the Committee These difficulties have been largely wiped out following the information received in reply to the letters sent out to the secretaries last September With the completion of this definite list more opportunity will be given the men down state to fill appointments

"The office of the Educational Committee has been prepared to release news items concerning any medical meetings to newspapers in the State The editors are glad to receive these notices and the public is interested in knowing what the profession is doing Many societies have taken advantage of this service and have felt the benefits obtained from good publicity in their own and surrounding counties

'The Committee believes that County Societies would do well to plan their programs for an entire year, scheduling interesting subjects and good speakers, being careful to see that some phase of obstetrics is discussed one or more times, also some phase of pediatrics should receive attention"

The report closed with a list of 45 programs prepared by the committee, at a cost of $541 13

THE TREATMENT OF MINOR INJURIES*

By JOHN J MOORHEAD, M D., NEW YORK, N. Y.

IN a general way minor injuries may be said to comprise the ambulatory group of the injured, always however having in mind the possibility of a minor becoming a major injury usually as the result of infection or other complication

If we attempt to classify these so-called minor traumata we find that statistics vary because a group selected from a given industry will differ from a group selected from another industry or from the general community It is pertinent to say that the terms "Industrial Accidents" and "Industrial Surgery" are passing out, for industrial accidents no longer bulk large by comparison with automobile accidents We might aptly talk of "Automobile Surgery," but shortly we must need talk of "Aviation Surgery" just appearing on the horizon Several decades ago "Railway Spine" was a popular term, but no one to-day uses that title to describe the almost obsolete traumatic hysteroneurasthenia

In an attempt to collate the frequency of various kinds of minor injuries, I have selected 3,555 cases treated under my supervision, of these 1,039 were lacerations, 235 were sprains, 204 wound infections, 121 fractures

For our purposes to-day, I would limit our discussion to certain fundamentals of treatment as applied to

I	Wounds	V	Synovitis—Bursitis
II	Burns		
III	Foreign Bodies	VI.	Dislocations
IV	Sprains	VII	Fractures

There are several basic factors in accident surgery and of these may be mentioned and stressed

A The maximum of immediate care and attention means the minimum of disability and deformity

B Antiseptics are of limited value and cannot take the place of adequate sterilization obtained by plentiful use of soap and water

C Immediate complete suture of wounds is a dangerous procedure

D Adequate rest of injured parts is promoted by splintage and suspension.

E Regulated active motion encourages healing and minimizes the necessity for physiotherapy

F The first 48 hours usually determines the outcome as thereafter the subacute stage is reached in most of the traumapathies

G Tight dressings promote stasis leading to edema and this in turn invites infection or retards repair

These seven principles seem very simple very trite, as they are recorded, but they comprise the essentials and if respected keep a minor injury minor from a pathologic as well as from a chronologic standpoint

Let us proceed in some detail to the treatment of typical minor traumapathies

Wounds—At the outset let us remember that every wound is already infected unless made under aseptic precautions Hence our problem is solely the treatment of infected wounds We know that it takes at least six hours to demonstrate organisms in a wound recently acquired, therefore our intervention should be made within that period if we expect to retain a sterile field There are only two methods of sterilization, one mechanical (as by sponging or excising), the other chemical (as by antiseptics) We know also that bacteria only thrive in the presence of devitalized tissue, and on this depends the rationale of debridement or exsection of destroyed or damaged material

Take for example a wound of the hand due to a puncture from a nail. All these punctured wounds should be subjected to prolonged immersion in soap and water, grease being first removed by gasolene kerosene or an automobile soap Next the dried tract of this puncture should be thoroughly irrigated with some antiseptic of proven value Personally I employ iodine in full strength, using a hypodermic if necessary Next a wet dressing is applied, and here again iodine is used in a strength of one dram to a pint of saline solution The hand is

VITA GLASS

Vita glass has been subjected to numerous accelerated weathering tests by the U S Bureau of Standards, by Professor Stockbarger of the Massachusetts Institute of Technology, and by many other physicists These physical or quantitative tests, as well as biological experiments with rats and chickens, have established the fact that the solarization (weathering or seasoning) of Vita glass takes place quickly, and that after a few weeks' of actual use its transmission of ultra-violet light becomes constant.

Vita glass is being marketed primarily as a health prophylaxis, and not as a therapeutic agent, although it is now serving in the latter capacity in numerous well authenticated instances—particularly in the solaria of more than 200 hospitals in England and the United States—See page xix—*Adv*

KALAK WATER

Many diseases are complicated by an "acidosis" An important part in their treatment consists in replacing those elements needed to maintain the alkali reserve

In clinical practice a rational and agreeable method of alkalinization is afforded in Kalak Water—See page iv—*Adv*

BABYGAIN

The physician may safely prescribe BabyGain in cases where he deems it advisable to discontinue or complement breast feeding

BabyGain is more easily digested than modified fresh cow's milk, due to the reduction in the size of the butterfat globules and the breaking up of the casein floccules in our process of dehydration

BabyGain, restored to liquid form, agrees with the standard average analysis of mother's milk and its physical characteristics

The use of BabyGain will help to prevent summer diarrhea—See page xvii—*Adv*

HOFFMANN-LA ROCHE, INC

The Hoffmann-La Roche Chemical Works of New York City, are now completely established in their new home at Nutley, N J, where the entire organization—Laboratories, Production Department and Executive and Office Personnel—is housed The firm has also shortened its name and will be known henceforth simply as Hoffmann-La Roche, Inc, of Nutley, N J

A cordial invitation is extended to all members of the medical profession to visit Nutley and inspect the most modern of Scientific Laboratories—See page v—*Adv*

FOXGLOVE FARM

Foxglove Farm! Sounds interesting, doesn't it? Yes, the whole story of Foxglove Farm is different and interesting and the Upsher Smith Company, whose ads appear in these pages each month, will gladly tell the story to any physician who writes in on his prescription blank or letterhead for literature and trial package

Ascertain for yourself why Upsher Smith claims superiority for his products by finding out how this man, who has spent a lifetime in the study of Digitalis, carries the whole story through from seeding and planting to standardized finished product.

The address, 554 Sexton Bldg., Minneapolis, Minnesota, will direct your mail so that you may learn these facts—See page III—Adv

DIABETIC DIET READJUSTMENTS

Some foods cannot be allowed in diabetic diet at all and others only sparingly This means a readjustment in dietary habits that is difficult for the patient and trying for the physician. Practically all of the restricted foods may be duplicated by using Lister's Flour Each of these starch and sugar-free foods looks and tastes like the food that it replaces in the diet. With the variety of foods, possible through the use of Lister's Flour, the patient is satisfied There is no temptation to "cheat" and the case is better kept

Laboratories fully equipped. Ample facilities for the personal study of cases.
Address: SECRETARY, 24 HIGH STREET, BUFFALO N Y

reaches the zone of infection, virtually an osteomyelitis, and then if necessary we can remove the necrotic diaphysis and leave the epiphysis which may be sufficient to preserve the contour if not the function A rubber band is now placed in the incision, and two or three days later it is removed and the wound strapped This procedure gives prompt relief and the operative scar soon disappears

Now, wound treatment implies the use of *some* antiseptic Personally I have no great faith in germ killers because all of them are deficient in that they reach only superficial organisms, and if used in full strength, kill the tissues as well as the germs The best proof of their inefficiency is their number, each in turn being vaunted as the latest and the best What has become, for example, of carbolic acid and bichloride? Who now uses Dakin's Solution as a routine?

The present craze for Mercurochrome, the 1927 model, is but repetition It is virtually a wound rouge, and some of the extravagant claims for it suggest that the profession is expected to have reached the flapper stage or to have become Bolsheviks It is a dangerous drug because it contains mercury in relatively large amounts and yet we are circularized to use it not only externally but intravenously

Let us not forget however, that a first aid antiseptic is of value as a substitute for soap and water cleansing To that extent, at least, any reliable chemical has value—but to conclude that antiseptics are specifics is but to delude ourselves and to make a mockery of the experience gained during scores of years

Sunlight, and open air and sea water are nature's cures and we should avail ourselves of these agencies when possible Personally, I would prefer to leave all wounds open to the air if conditions permitted, and I know that face and scalp wounds are more benefited by no dressings than by any dressings Wound stimulants, like Balsam of Peru and Scarlet Red, are really only wound fertilizers, and if used at all should be subject to limitations

Burns

These are infected wounds due to thermal, chemical or electric contact They like all other wounds pass through three stages in their evolution The first stage is the dermatitis stage of pain, redness, swelling and blebs The second is the exudation stage The third is the granulation stage We accordingly treat the case based on these three stages, referring especially to second and third degree burns We do not favor paraffin or other occlusives

In the first stage we use a wet dressing of 10 per cent sodium bicarbonate, keeping it wet by inserting a perforated rubber tube into the meshes of the gauze We give morphine enough to control pain and we force fluids After the third day we expose the wound to the rays from an electric light, one hour out of every four, and then for longer periods In very extensive burns we frequently use no dressings at all, especially in children, but make a tent over the bed and place a series of electric bulbs within so that there is a more or less continuous raying of the parts We do not open blebs until the third day if possible, and are then careful to puncture them aseptically at their base

In the third or healing stage, we again rely on electric light, and when possible, on sunlight At night, or when a dressing is required, we use equal parts of sterile olive oil and camphorated oil This is a non-sticking, stimulating application quite useful in any granulating wound

In every case we see to it that the parts are freely moved to avoid contracture, and this is especially necessary in wounds about the neck and chest, the armpits, the groin, the knee

Tannic acid treatment is advocated by many excellent surgeons, a chemical debridement resulting therefrom

We reserve exsection of the burned area, debridement, for localized burns in that class in which adequate facilities are available and the condition of the patient permits The denuded surface is grafted at once if large, or is allowed to granulate if small

Obviously this procedure has a limited application as to patients and surgeons

Foreign Bodies

Search for these should be attempted only after definite localization, and even under the best of conditions, the search is often tedious and even fruitless If the wound is already infected, prudence dictates restraint and thus we wait 7-10 days unless we can proceed within the first 24 hours

Joints

Sprains are essentially lacerations with stretching and torsion of ligaments If seen early, an excellent routine is hot applications followed by massage with warm camphorated oil, in turn followed by exposure to dry heat or the rays from a 50 Watt unfrosted electric light bulb Then a strapping or bandage is applied with the ligament so braced that the torn or stretched edges are coapted Immediate motion is insisted upon, otherwise effusion organizes and a complicating set of adhesions will delay recovery

A sprained ankle is typical of this variety and the above named measures are very helpful in this group Disability will be reduced one half by this mobilization treatment by comparison with the customary immobilization or plaster cast method

Subacute and chronic sprain usually responds to massage, radiant heat and strapping or bandaging

Back sprain or strain is a tormenting problem,

kept quiet, and another dressing of the same sort is applied next day If on the third day signs of infection are absent we may be reasonably sure that recovery will be uneventful In passing, be alert for local tenderness as an important early sign of impending infection Do not disregard the patient's statement as to throbbing or heat, for both are warning signals

A lacerated wound of the scalp or leg due to an automobile accident serves as an example of the next group Here again plentiful use of soap and water is the primary consideration We should spend from 10 to 30 minutes in cleansing such a wound, especially if there is associated contusion of surrounding integument Always widely separate the edges of such a wound, and in the scalp inspect and palpate for possible fracture Leave no blood clot, for of all things this and macerated muscle are the best culture media, virtually autogenous bouillon

If there is a contusion and laceration, place the sutures (non-absorbable) but do not tie them until the third day This is the principle of delayed suture as compared with immediate suture, and if we practice it we will attain practically primary union and rarely obtain infection If immediate suture is applicable, drain always, using a rubber band or a strand of the suture material Remove this drain on the second or third day Needless to say all sutures should be of the interrupted type, using non-absorbable material

Let us assume that the wound becomes infected, or is infected when we start treatment Much depends on the site and type of the wound, but more depends upon the prevalent organism If streptococci are present, alone or with staphylococci, we should remove stitches widely and promptly If on the contrary, staphylococci and other organisms are present, we can be less radical and more leisurely In the early stages of infection before pus is present, I would advise removal of some of the stitches and the use of hot applications of saturated solution of magnesium sulphate This is used as a bulky wet dressing or the part is immersed in it If the former is chosen, insert a perforated rubber tube in the gauze meshes and through this inject the solution often enough to keep the dressings moist

I feel certain that hot dressings over a period of 24-48 hours focalizes the infection so that if incision and drainage become necessary, we will operate in a zone where "pointing" or softening has occurred We should incise for infection only under 3 conditions, namely for localized fluctuation, localized pain or localized induration To incise on suspicion, or for redness or for generalized pain or swelling, is but to spread and not to control infection

This applies especially to infections of the hand, and of all places we should be alert in this area More and more I find myself allowing infections to self limit of themselves before interfering, and when incision is made, an effort is made to keep within the area of softening This to me is the ideal treatment for boils and carbuncles and I rarely incise these at all but on the contrary let them burst of themselves

In gunshot wounds, in those likely to be contaminated by garden soil or manure, it is prudent to give tetanus antitoxin

A few practical rules in hand infections may be pertinent In the first place, suture hand wounds very cautiously and practically all of them are best treated by the delayed suture method already outlined Splintage is an added precaution and to those of you who are doing much accident work, let me suggest the value of sheet aluminum to fashion splints to fit the patient rather than having the patient fit the splint Rarely cross cut in hand infections Rarely cut on the dorsum of the hand, for in nearly all palm infections the dorsal swelling is edema and to open into this is but to extend and not diminish the process Infection from a given finger takes a certain anatomical route of least resistance, and thus there are three foci or reservoirs into which pus will drain These fascial spaces on the palm—thenar, hypothenar and mid palmar—are well defined and easily reached by a route known to all We are warned as to which to attack by local fluctuation, local pain or local induration, and we should not attack until we are thus warned

Make the incision under a general anesthetic using a tourniquet Let the incision be adequate, and if it is, it will gape of itself Use no gauze drainage except for hemostasis Gauze then should be soaked in oil or vaseline If through and through drainage is needed, use rubber bands and they need not be removed until infection has subsided Ramming gauze into a wound is taxidermy and not surgery

In finger infections, use lateral incisions and spare the creases at the joints

Wet dressings of some mild antiseptic favors softening and exudation. Salt solution, sodium bicarbonate (10%) solution, magnesium sulphate (saturated) solution probably act just as well

At each dressing, let the part be immersed in hot water so that the gauze can soak off and so that the fingers may be moved

Motion should start at once, otherwise contractures will get ahead of us and we will then have a troublesome and perhaps a deforming complication

Felons announce themselves by a history of a forgotten or neglected puncture, a painful throbbing, sleepless nights, and then the patient presents himself with a finger held aloft A bisecting of the finger pulp is the best treatment for it

reaches the zone of infection, virtually an osteomyelitis, and then if necessary we can remove the necrotic diaphysis and leave the epiphysis which may be sufficient to preserve the contour if not the function A rubber band is now placed in the incision, and two or three days later it is removed and the wound strapped This procedure gives prompt relief and the operative scar soon disappears

Now, wound treatment implies the use of *some* antiseptic Personally I have no great faith in germ killers because all of them are deficient in that they reach only superficial organisms, and if used in full strength, kill the tissues as well as the germs The best proof of their inefficiency is their number, each in turn being vaunted as the latest and the best What has become, for example, of carbolic acid and bichloride? In every case we see to it that the parts are freely moved to avoid contracture, and this is especially necessary in wounds about the neck and chest, the armpits, the groin, the knee

Tannic acid treatment is advocated by many excellent surgeons, a chemical debridement resulting therefrom

We reserve exsection of the burned area, débridement, for localized burns in that class in which adequate facilities are available and the condition of the patient permits The denuded surface is grafted at once if large, or is allowed to granulate if small

Obviously this procedure has a limited application as to patients and surgeons

Foreign Bodies

Search for these should be attempted only after definite localization, and even under the best of conditions, the search is often tedious and even fruitless If the wound is already infected, prudence dictates restraint and thus we wait 7-10 days unless we can proceed within the first 24 hours

Joints

Sprains are essentially lacerations with stretching and torsion of ligaments If seen early, an excellent routine is hot applications followed by massage with warm camphorated oil, in turn followed by exposure to dry heat or the rays from a 50 Watt unfrosted electric light bulb Then a strapping or bandage is applied with the ligament so braced that the torn or stretched edges are coapted Immediate motion is insisted upon, otherwise effusion organizes and a complicating set of adhesions will delay recovery

A sprained ankle is typical of this variety and the above named measures are very helpful in this group Disability will be reduced one half by this mobilization treatment by comparison with the customary immobilization or plaster cast method

Subacute and chronic sprain usually responds to massage, radiant heat and strapping or bandaging

Back sprain or strain is a tormenting problem,

e symptoms are almost wholly
must carefully exclude fracture
process even when the violence
ntly non-causative If there is an
is of the spine, it is not unusual
r-ray small fragments apparently
from a stalactite of bone from an
ebra It is in this group that we
y in allotting to an injury, often
host of painful and often disabling
The clinical fact seems to be that the
patient often activates by injury an
quiescent focus

In this group our prognosis must be the
uarded and our therapy the less routine
are called upon to treat arthritis plus in-
ather than injury minus arthritis, we will
that time and trouble enter into the situa-

I am convinced that many of the injured
virtually "carriers" and that trauma in them
ns an activation of an old process at the site
njury This is not by any means limited to
ute trauma, for it occurs also in fractures and
n wounds

The so-called "poor healer" is often the patient with residual foci of infection which by metastasis invades the scene of trauma and proceeds to complicate what would otherwise be an ordinary occurrence A simple hematoma that becomes an abscess is an example of this group, and the basis for this general manifestation is probably the efficient nutrient media supplied by any injury that produces effusion of blood and serum, especially if macerated or bruised soft parts enter into the menstruum

Here we have all the elements needed for propagation of bacteria, virtually an autogenous culture medium, compared to which beef bouillon of the laboratory test tube is a feeble substitute

Synovitis, as of the knee, is practically always sanious when due to injury It is rarely due to direct violence, and in my opinion is often a symptom of an internal derangement of the joint, such as a loose cartilage, hypertrophied subpatella fat pads or some intrinsic arthrolith Virtually all of these act as joint calculi capable of causing the same set of symptoms as calculi in the gall bladder or urinary tract

Be on guard then for "recurrent synovitis" for it usually means an arthrolith that upsets the gliding motion of the knee, trips the patient, causes a fall and the contact with the ground is accused rather than the real initiating factor It is the same as in fracture of the patella, the patient believes the knee cap was broken by contact with the ground, we know the fracture was present and caused the fall

In selected cases, the best treatment for synovitis of the knee is immediate aspiration followed by immediate functioning of the joint

To aspirate a knee, let the patella represent the dial of a clock, figure XII on top, VI below Paint the clock with iodine. Inject at the outer side of the middle of the for the left knee and IX for the right k gram 1) In this area introduce the

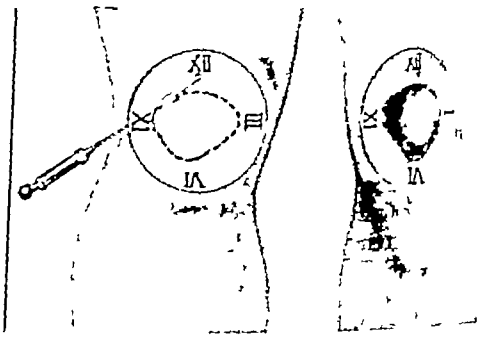

DIAGRAM 1
Aspiration of knee, showing direction of needle

needle and point it upward toward XII, p the patella outward just before thrustin needle so that a guiding shelf will be fo Extract all the fluid through this puncture by pressure or aspiration Remove the and seal the opening with collodion Then the patient move the knee and if it is relati painless, permit walking From now on massage and dry heat can be used This is effective method, just as safe and simple as pirating the pleura if done aseptically It is office procedure and once practised will your routine Re-aspiration is rarely needed no splintage of any sort is required By with strapping or other forms of immobi this method is much more efficient and can applied equally well to subacute or chronic ca

Bursitis, as of the knee, is treated in the manner In the elbow, be guarded as to p recovery because infection very often supe in old or neglected cases In the shoulder subdeltoid or subacromial group usually respond well to postural treatment that requires abduction of the arm To this add massage, dry heat and diathermy In passing it may be stated that diathermy is no cure-all and of all forms of physiotherapy we rely mainly on massage and dry or moist heat in all kinds of traumata Physiotherapy is best applied by self-use of the affected part, and if mobilization is begun early, physiotherapy is relatively unimportant It is not good surgery for us to so manage our case that it takes as long to get over the treatment as it does to get over the injury

DISLOCATIONS

There are certain basic rules for the reduction of any dislocation, a shoulder for example These may be said to consist of the following

(1) *Anesthesia* Nitrous oxide is safest, Ether by the drop method is next, Ethyl Chloride next,

Chloroform in all forms of trauma is as dangerous as it used to be safe in obstetrics Give the anesthesia only to the stage of relaxation

(2) *Increase* the original deformity In other words, make the condition worse before trying to make it better

(3) *Traction and Manipulation* This essentially is traction plus flexion, extension or rotation

Test the success of the reduction by noting

(a) Absence of deformity
(b) Restoration of landmarks
(c) Return of function
(d) Relief of pain as narrated by the patient

The familiar Kocher method is the best means of reducing the average dislocation, and we recall that over half of all dislocated joints everywhere are of the subcoracoid variety When this method fails after two or three cautious trials, then place the patient on his back on the floor and raise him therefrom by using the affected arm as a handle This is traction, elevation and abduction If for any reason anesthesia cannot be given, place the patient face down on table and let the arm hang over the edge, and hang on it a weight of 10-20 pounds fastened to the wrist Here again we have traction, and the average irreducible dislocation will yield in from 10-30 minutes

The point is that in dislocations and in fractures we do the setting not by replacing the bone, but rather by stretching out the contracted muscles which maintain the deformity

The aftercare requires us to employ massage and gradual motion from the very beginning and for that reason, casts and other dressings which hide the part should not be used.

Let us remember that every dislocation is associated with arthrosynovitis, and as stated previously, the treatment for this is massage and motion In all of these joint conditions (dislocations and others) and in the myalgias we have been using a routine which we call "S O L" "S" means soap suds applied as a hot pack or as an immersion "O" means massage with warm camphorated oil "L" means exposure to the rays from a 50 Watt bulb or direct sunlight Each of these items takes 10 minutes so that a complete "S O L" seance takes half an hour at least

Fractures

Essentially a fracture is a laceration of bone and the object of treatment is coaptation We attempt an end to end anastomosis, knowing that a side to side anastomosis invites non-union, deformity and disability There are after all only two types of fracture, either of which may be simple or compound

Type I is the displaced variety in which the fragments are overlapped and do not touch at the ends

Type II is the non-displaced variety in which the fragments are not overlapped and the ends are in contact.

Type I needs Reduction and Retention, Type II needs Retention only

The object of treatment is to convert Type I—the overlapping—into Type II the non-overlapping There is only one way to accomplish this setting, and that is by traction, and every imaginable kind of traction is either *manual* or *mechanical*

After reduction, comes retention or splinting, and the essential of this is safety, hence every splint should first of all be safe, and second it should be simple For that reason, make the splint fit the patient, and do not try to make the patient fit the splint Moulded two piece plaster of Paris splints accomplish this tailor-made requisite Sheet aluminum is the next best—basswood the third, and sheet felt the fourth

In the fracture lexicon there are four R's, first is *Recognition* or diagnosis The second *Reduction* or setting The third *Retention* or splintage The fourth, *Restoration* or functioning After we set any fracture, let us quickly go on to relieving the associates of every bone laceration, namely repair of lacerated muscle and relief of effused blood and serum If we neglect these we are just as culpable as if we took out a ruptured appendix and failed to take out the surrounding pus

Hence, we set the fracture, and we do it *now*, not tomorrow, not awaiting the *x*-ray nor the special splint, nor do we "wait until the swelling goes down" If we do it *now*, we can do it easily before edema exists or contractures occur, the *now* means that we are treating the fracture minus complications If we wait, we must treat the fracture plus complications

X-rays *before* setting have a place of course, but they are much more valuable *after* setting We should use our eyes and fingers for diagnosis more than we do All of us are developing the atrophy of non-use since these easier laboratory methods are so comfortable and so exact. It is much better to use *x*-rays for determining the success of reduction rather than for the success of diagnosis In passing, let us not forget that many so-called "severe sprains" or "partial dislocations" are in reality fractures It is a safe rule that every deforming and disabling joint injury should first be regarded as a fracture rather than a dislocation, the only important exception to this is in the shoulder joint For example, the average so-called dislocation of a finger, wrist or ankle proves to be a fracture Another thing let us recall that any involvement of cartilage in a fracture means inevitable deformity Look at baseball fingers commonly regarded as dislocations, sprains, ruptured tendons or synovitis Or take a Colles fracture comminuted into the joint, and despite most accurate adjustment, swelling and deformation persist The answer is that in both instances fibrocartilage is involved, and cartilage everywhere heals irregularly Witness the

tainly is even more dangerous if used often by the surgeon

FOREARM

In fracture of the radius or ulna, or both, a "sugar tongs" (Diag 7) or else a moulded 2-piece plaster of Paris splint is used reaching from the duction, if these fail, then open operation and notching of the fragments is necessary It is rare in my experience to manage this class of case without operation, especially in the radius

In a fracture of the shaft of the ulna be on guard for an associated dislocation of the head of

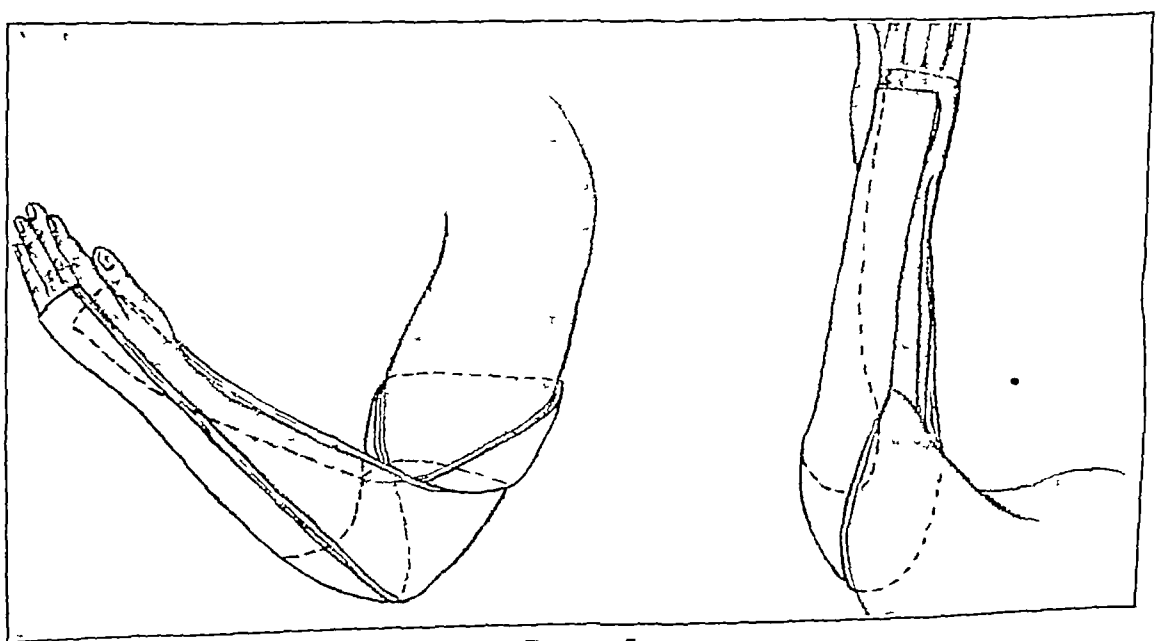

DIAGRAM 7
Sugar tongs moulded plaster of Paris splint for fractured forearm

the radius I have missed this combination once with a discomforting outcome and last Spring saw two cases in consultation where the outcome was equally a cause of chagrin This combination is just like the more frequent association of a fractured lower 1/3 of the tibia and a coincident fracture of the upper end of the fibula

In passing, let me urge that an initial test be made for musculo spiral and ulnar nerve function in every upper extremity injury, if discovered after treatment is instituted, blame will be harder to allot.

In head of the radius fracture without displacement, we use the same splintage described for fractures of the shaft of the forearm If displacement is marked, operation is needed and usually the bone fragment is removed as it cannot often be replaced and virtually acts as a foreign body

Colles Fracture

Early reduction here of all places means easy reduction In a few hours there is so much arthrotenosynovitis that great effort is needed to overcome the pull of the 28 tendons crossing this joint The steps of reduction are the same as in any other fracture, namely

(1) Anesthesia up to the point where the patient cannot count out loud correctly, and this is generally after 24 is reached, starting at 1

(2) Make the deformity worse by pushing the hand upward and backward, and do not hesitate to bend the hand so far backward that it almost touches the forearm

(3) Rotate the hand freely until crepitus is very freely felt or is audible Now the fragments will be easily disentangled. Then pull down slowly and firmly, the elbow being held at a right angle so that counter-traction is thus obtained Let this pull be continued until a sense of giving is felt, and then place a thumb over the lower fragment and force it forward, meanwhile still pulling down with your hand in the patient's hand Then bend the wrist as far forward as possible and push it inward

Now test for reduction by noting disappearance of the bony knob on the wrist and the return of the normal levels of the styloids Finally the best test is to push the hand toward the fracture, as if to impact the fragments, if they do not override again, we can be reasonably sure they are reduced

A two-piece moulded splint is now applied, reaching from the knuckles to below the elbow (Diag 8) The downward and inward tilt of the hand is maintained by having the patient clench the fingers against a roller bandage placed over the palmar splint This position is a fine example of the precept to leave a fracture when set in exactly the opposite position it was in before setting—the original position of the hand was outward and backward, we convert this into inward and forward Motion of the fingers is begun by the patient at once and massage and daily thereafter when possible

After 7-10 days we remove the splint and try guarded passive motion a few days later, so that the end of 14 days is usually permitted the "O L" treatment already mentioned splintage is removed usually by the eighth day and generally we cut it away in such that the final piece is a mere cuff to be worn at night or when out of doors There are patients with an arthritis tendency who develop a most troublesome and persistent swelling of the joint despite early accurate reduction virtually a metastasis from a focus elsewhere it may take weeks before function is restored

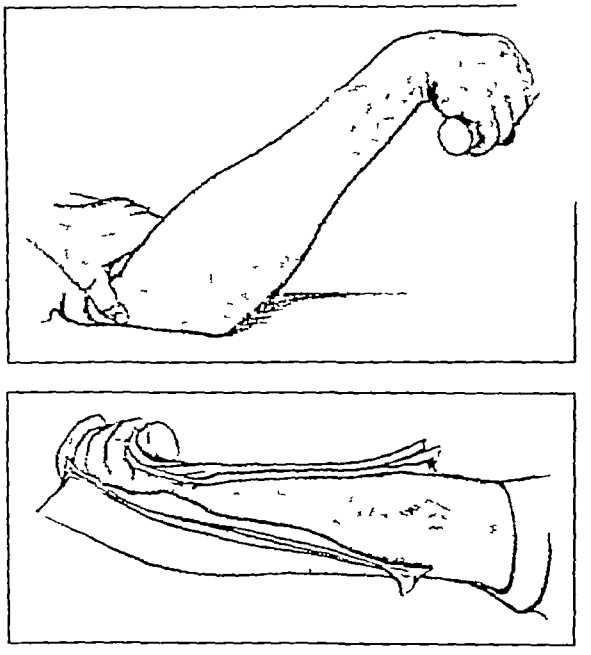

Diagram 8

ANKLE FRACTURES

Of these Pott's fracture and variants thereof are the most common, and while these are not strictly ambulatory, yet the practitioner is frequently called upon to treat them outside of the hospital

The first thing to do is to obtain reduction, and if anesthesia is unobtainable or inadvisable at the moment, an excellent preliminary is to fasten a towel around the ankle and foot, and to this attach a cord leading to a weight of 5-20 pounds The leg and foot are now placed on a grooved pillow, the lower end of the bed is elevated a foot or more, and the cord and weight are hung over the end of the raised bed (Diag 10) This is improvised traction and counter-traction, and if used in the lower limb from the outset and continued 12-24 hours we will be gratified to see the alignment thus obtained

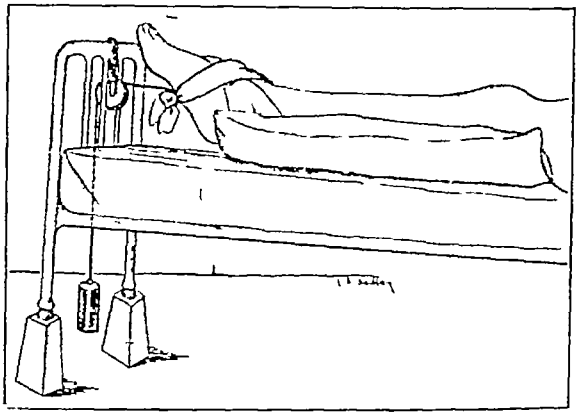

DIAGRAM 10
Provisional traction by bandage or strap around ankle

If manual reduction of a Pott's fracture is to be attempted, the steps are as follows

(1) Anesthesia as already described

(2) Increase the deformity by pushing the foot further outward and backward Do this freely, having the thigh completely flexed on the abdomen to fully relax the Achilles tendon I would stress this point, for if we do not relax the heel cord we cannot obtain the needed freedom for the next step

(3) Now pull down firmly and slowly on the foot, lifting forward at the same time until a sense of giving is felt This giving sensation is apparent to your grasp, it often is visible, occasionally audible also Then flex the foot as far upward and inward as possible, for we must not only correct the original outward and backward displacement, but actually over-correct it

The tests of reduction are

(1) The deformity is absent

(2) The bony landmarks are restored

(3) Jones' test in which the pressure of one finger against the sole keeps the foot at a right angle

(4) Pressure upward on the foot does not reproduce deformity

Splintage is by a two piece plaster of Paris splint, the posterior half of which passes from just below the knee down the calf and along the sole to the web spaces The lateral half passes around the instep and up the inner side of the leg

This is the Stimson splint than which there is none better

Massage can begin in a few days, the lateral half of the splint being removed for this purpose In 7-10 days, some guarded passive motion is tried, and if it produces no reaction, then guarded active motion is allowed 7-10 days later Thereafter the lateral splint is removed and the whole foot and leg can be immersed in hot soap suds or hot water daily if possible

Weight bearing is gradually allowed when there is no reaction on pounding the heel and when the patient can painlessly push the sole against the foot of the bed or against the examiner's hand

It is a wise precaution to build up the inner half of the sole and heel of the shoe and to carefully instruct the patient to walk on the outer side of the foot after the manner of a patient with flat feet.

This then, in sketch fashion represents favored procedures in the management of some of the common minor injuries

CONCLUSIONS

(1) *Wounds* are best sterilized by plentiful use of soap and water Antiseptics may be colorful and much vaunted, but in reality they are unreliable.

Secondary suture is safer and gives almost as rapid healing as primary suture.

All traumatic wounds are already infected and hence should be drained.

(2) *Hand Infections* should not be ruthlessly incised, but on the contrary the attack should be along anatomical routes

(3) *Joint Injuries* should be subjected to early mobilization if we would escape the long drawn out sequalæ of arthrosynovitis

(4) *Fractures* should be set at once, and in nearly all of them, improvised traction will accomplish reduction during the period in which we usually do nothing except to apply preliminary splinting

(5) *Burns* are infected wounds and should be so treated Debridement has a limited field.

(6) *Foreign Bodies* should first be well localized and removed only in the pre- or post-infected stages

(7) *Traumatic Surgery* is acute surgery demanding immediate treatment if complications leading to disability and deformity are to be prevented.

POST-OPERATIVE RENAL INFECTIONS*

By HENRY DAWSON FURNISS, M.D, F.A.C.S., NEW YORK, N. Y.

EACH year every surgeon experiences a certain number of post-operative urinary infections, and it is an interesting study to determine in what class of cases such a complication most frequently occurs and to fathom out the causes At times such infections are unavoidable, more often avoidable, and generally amenable to prompt and rational treatment. The infection may arise in any part of the urinary tract, and be of any degree of severity Certain operations are attended by a high incidence of urinary infections At times the infection has only a casual relation to the operation and may be due to an entirely unrelated cause

In all infections a number of factors are usually operative The blood stream is constantly picking up bacteria, destroying and eliminating them without harm to the body When for any cause the body resistance is low, due to such factors as chilling, fatigue, anesthetics, etc, or the virulence of the bacteria is great, damage to the urinary tract may arise This possibility is enhanced if there are factors that interfere with drainage in any part of the urinary system This may be due to nerve lesions, cerebral, cordal, or peripheral, obstruction due to strictures, foreign bodies, or pressure of outside agencies, as growths, packing, etc Except for direct traumatism, deficient drainage is one of the prime causes of infection

Numerous experiments have been done that prove that the simple introduction of pathogenic bacteria into the urinary tract is not enough to cause cystitis, even this with traumatism is not always sufficient. One is often astonished at the slight reaction that follows severe traumatism, as is noted in the fulguration of papillomata, and Hunner Ulcers

There is a relation between the type of operation and the incidence of urinary infection, and it will be noted from the accompanying table that the infection occurs most often following the operation that lowers the body resistance, damages the tract directly, and interferes with the drainage mechanism This refers to the pelvis of the kidney, the ureter and the bladder As such damage most often is done to the bladder cystitis is more common than renal infections The Wertheim operation for carcinoma of the cervix is the outstanding example—it lowers the resistance, damages the bladder directly, and retention is the rule after a properly done Wertheim's In fact, Paul Werner* claims that if retention does not follow he feels that a proper operation has not been done The Watkin's Interposition is a close second and other vaginal plastics, especially those on the anterior wall, and hysterectomies, not far behind

Injuries to the ureter, resulting in obstruction, and fistulae are followed by ureteral obstruction and kidney infection

* Read at the Annual Meeting of the Medical Society of the State of New York, at Albany, May 22 1928.

* *Surg Gyn. & Obst*, Jan. 1928.

How does the infection gain entrance? This occurs through catheterization, infection through the blood stream, or the passage from a neighboring infected tissue, the first two being the more frequent If the infection arises in the kidney it may descend the ureter and involve the bladder and urethra, on the other hand I feel that a cystitis may cause a pyelitis by ascent of the infection along the ureter For example, after a difficult forceps delivery a patient developed an acute cystitis, and in a few days, a bilateral pyelitis There was marked edema of the trigonum A nephrectomy was done and the same edema was seen in the portion of the dilated pelvis near the ureteropelvic junction and in the ureter, this to my way of thinking, proving the infection an ascending one The majority of the renal infections are, I believe, haemotogenous, and arise from the lodgment of bacteria, having their origin in infected thrombi related to the operation The sudden, abrupt, acute onset without symptoms referable to the bladder (and a bladder that cystoscopically appears normal) leads to this conclusion After a few days the second kidney often becomes involved, either through the blood stream or from an ascending infection

Occasionally a urinary tract infection may follow a tonsillitis

To get an idea of the number of infections, and the class of operation in which they occurred most frequently I have tabulated 200 consecutive private operations

Frankly, I was rather surprised at the small number of renal infections noted I am sure there are more on the ward cases, and this may be due to the fact that it is difficult to impress upon the internes and nurses the necessity for adequate catheterization When a patient begins to void, the interne is apt to discontinue the order for catheterization, the patient having residual urine is more prone to infection Better nursing care of the private cases may also have a bearing upon this

A perusal of the list will show that in the smaller operations, and those requiring short anesthesia, there was little bladder disturbance In all the radium cases for so-called functional bleeding, the bladder was drained with a retention catheter during the time the radium was in the uterus, and yet none of these developed a cystitis In the operations that involved the bladder, as the abdominal hysterectomies, and more particularly, interposition and Mayo Cystocele operations, ones that both injured the bladder and interfered with proper evacuation, the incidence of infection is greater

Kidney infections are more apt to develop in the cases where ureter drainage is deficient —note the number following the carcinomata of the bladder, especially where the growth is in the region of the ureteric opening

Symptoms —In the mild cystitis cases there is first noted bladder discomfort and if the patient is able to void, frequency of urination Cystitis alone causes no temperature unless it is severe, as in the gangrenous type There is pus in the urine and often blood is noted the first day or two The pain may be slight or severe, usually paralleling the severity of the inflammation In the severe and gangrenous type there is foul smelling urine containing a good deal of pus, and the patients are quite ill Such cases usually follow very difficult labors or impacted growths

In the pyelitis cases which follow a cystitis it may be noted that the pain travels from the bladder region along the course of the ureter and when the kidney becomes involved there is pain, with chills and temperature, reaching 101° and even 106°F, usually dropping to normal or near normal, and followed by recurrences Leucocytosis is usually present With the haemotogenous type, several days after operation, the patient is found with temperature that may have followed a chill Tenderness in the kidney region may be marked or so slight that jarring by first percussion (Murphy's sign), or deep pressure is required to bring it out. This tenderness usually disappears after a few days, or may continue in the more severe cases Subsequent involvement of the other kidney is frequent. Urgency and frequency soon develop In the haemotogenous type pus may not be found in the urine during the first few days, as the infection is primarily limited to the kidney cortex The majority clear up spontaneously, though a few severe ones persist until actively treated

Diagnosis —This can usually be made on the symptoms Frequency, pain, pus in the urine, and no temperature, usually speak for infection limited to the bladder Temperature, with or without chills and renal pain, point to kidney involvement With renal involvement a mental review of the operation is made to determine the possibility or probability of ureter damage In an uretero-sacral shortening where free venous oozing occurred, the left ureter was occluded in the attempt to control the bleeding—with a consequent severe renal infection When there is such a possibility the patient should be cystoscoped after injecting Indigo-Carmine, intravenously Should the dye fail to appear on one side, a catheter should be passed to determine the patency and the point of obstruction of the ureter At times a radiographic examination is essential, especially if there is a history of pre-operative renal colics—a quiescent stone may engage the ureter and cause obstruction Ordinarily,

even in pyelitis, I do not advocate cystoscopy in the first three days of the infection, but if there is no improvement at the end of this time the patient is examined—more to institute treatment than to clear up the diagnosis

Treatment—Prophylaxis—Before every operation upon women a catheterized specimen should be examined, to determine the presence or absence of infection, and should such exist, it should, if possible, be eliminated After a Watkin's Interposition Operation done by one of my confreres, a large amount of pus was found coming from the left kidney, on further investigation eight large renal stones were discovered that had been there probably for years In a recent case, from a neighboring city, two stones were found in the bladder after a beautiful correction of a large cystocele —these stones antedated the operation at least several months

The bladder should also be tested for residual urine, especially in cystocele and prolapse cases The knowledge of this residual tendency will be of help in the post-operative treatment The eyes and patellae reflexes should be investigated so that a tabes may not be overlooked After operation all factors lowering vitality, such as chilling, wetting etc, should be prevented Urinary antiseptics, such as urotropin, should be given where bladder damage has been done, where there is imperfect evacuation, and catheterization is necessary

Catheterization is more apt to be underdone than overdone To obtain the proper spirit of cooperation with the nurse, the problem of residual urine, and its dangers should be explained Also the so-called paradoxical incontinence At times it is difficult to make a nurse understand that a patient may not be emptying the bladder when she is having frequent urination or spillage In most of our vaginal plastics and hysterectomies, there is apt to be residual urine for a week or more, and it is my rule to have the patient catheterized every six hours until I am sure there is no residual urine This is determined by catheterization after voiding Catheterization must be gently done, it cannot be done gently without proper lubrication of the catheter Frequently the nurse will attempt catheterization with no other lubricant than the water in which the instrument was boiled, and the urethra is needlessly traumatized, rendering it more liable to infection and making subsequent catheterization more difficult and painful

During the period of catheterization the patient should take some urinary antiseptic, preferably, Hexamethylenamine and Acid Sodium Phosphate, and once daily the bladder should be irrigated with a mild antiseptic solution followed by the instillation of drams two of 15% Argyrol Solution

Cystitis—In the acute stage Tincture of Hycocyamus and Potassium Citrate are given, 15 minims of the former and 20 grains of the latter, every three or four hours The diet should be bland and fluids given generously The bladder is catheterized and irrigated with Boric Solution followed by instillation of argyrol If there is no residual urine, once daily is sufficient, otherwise, the patient is catheterized every 6 or 8 hours and irrigated once or twice daily after the catheterization Codeine, or even morphine may be necessary for pain As the more acute symptoms subside the sedative mixture is discontinued and Hexamethylanemine and Acid Sodium Phosphate are given Except in the severe cases the condition rapidly clears Its continuance makes one suspicious of renal involvement.

In pyelitis a conservative policy is advocated, plenty of fluids, heat to the affected region, exhibition of alkalies The urinary antiseptics are of slight value at this stage. Most of the pyelitic infections show some improvement in three days' time, and in the event of failure to do so, I feel that local treatment is indicated Some contend that the good results of ureter catheterization and pelvic lavage are due more to the establishment of drainage than to the effect of medicaments in the pelvis For this reason they advocate leaving the catheter in the ureter for one or more days The ureter is not a quiescent organ, and I feel sure that its peristaltic action over a stiff catheter causes marked ureteral damage Except in marked pelvic retention I prefer withdrawing the catheter after instilling the antiseptic fluid My best results have come from nitrate of silver When the pelvis cannot be readily emptied, the silver forms an insoluble chloride with the salt of the urine, destroying its efficacy, and leaving a precipitate that is difficult to be drained away In such instances some urine soluble substance should be used—mercurchrome being the best of these

These treatments are carried out every day, or less frequently depending upon the urgency of the case

There will be instances where it will be technically impossible to catheterize the ureter, and an attack must be made directly on the kidney Such are found in the bladder growths in the neighborhood of the ureteric orifices, or after injury to the ureter Where ligation of the ureter has been found, the question of reopening the wound to free the ureter comes under consideration Whether to do this or drain or remove the kidney often calls for a nice decision

In the renal infections that are severe and show no tendency to betterment, nephrotomy or more often nephrectomy is indicated.

Nephrotomy where the patient is too ill for nephrectomy, and where drainage of the kidney may result in its return to normal Nephrectomy, in many instances, is not much more of an operation than nephrotomy, and if the chances of saving the kidney are not reasonably certain, the removal of the kidney is preferable

Should a ureteral fistula develop the problem arises—to make an anastomosis into the bladder, or the intestine, or a nephrectomy Except in favorable cases of low injury, nephrectomy is the safer operation However, the recent favorable results on rectal implantation according to Coffey technic may offer a solution in the saving of the kidney In March, 1928, I did a bilateral implantation in two stages for irreparable vesico-vaginal fistula following labor and at present the result appears most satisfactory

Summary—1 Cystitis is frequent after operation Renal infection less frequent, except operations involving the ureter, or its vesical orifice

2 The greater number of infections follow operations of severity or those preventing proper drainage of the urinary tract

3 Prophylaxis should be directed to avoidance of urinary tract injury and the establishment of proper evacuation of the urine

4 The infection of the bladder may be through direct causes, contamination, or of haematogenous origin That of the kidneys through the blood stream, or ascent of the ureter

5 Treatment should be directed toward the removal of cause, proper evacuation, relief of symptoms, and medication, both general and local

6 Surgical treatment of these infections is, fortunately, seldom necessary, but when indicated should be undertaken without hesitation

ALCOHOLIC PSEUDO PELLAGRA*

By EDWARD R MALONEY, M D, LOUIS TULIPAN, M D, NEW YORK, N Y

From the Department of Dermatology and Syphilology, New York University Medical School
Service of Dr Howard Fox.

THIS paper is based on a study of a number of patients with the characteristic skin eruption of Pellagra who were admitted to the dermatological clinic of the New York University Medical School and later transferred to the dermatological service at Bellevue Hospital for further observation

All of them were addicted to the excessive use of alcohol and gave histories of having been on drinking debauches for periods varying from two to six weeks During this time they had had very little or no food

Twenty-one cases of this type were admitted and studied from June to October Of these, 20 were men and 1 woman Their ages varied from 24 to 67 with an average age of 45

They all gave a history more or less similar to the following —"For the past four or five weeks I have been drinking continuously without touching a morsel of food, except an occasional plate of soup or a slice of bread"

In this series, all the cases exhibited the characteristic and typical dermatitis on the dorsal aspects of the wrists and hands, extending to the phalanges There was a sharply defined border between the affected dorsal and the non-affected surfaces The eruption was symmetrical in all the cases

The eruption varied in appearance, from slight redness pigmentation and wrinkling of the skin to a violaceous erythema on a dark pigmented base, covered by scales or bullae, or eroded areas and crusts where previous bullae had ruptured When the cutaneous lesion began to subside, large sheets of desquamation were observed in most cases In one patient, bullae and oedema under both eyes were present in addition to the eruption on the hands In some of the other cases, patches of pigment and dermatitis on various parts of the body were observed. The end results in the majority of the cases were either a dry and somewhat atrophied skin, or wrinkling and pigmentation

All, but two of our cases were free from mental symptoms These two cases were diagnosed as acute alcoholism and presented the mental symptoms of delirium tremens and terminated in death

None of the cases had very marked intestinal disturbances, about one-half suffered from more or less mild diarrhoea, the others were constipated Recovery in all but the two previously mentioned cases, was very rapid the patients remaining in the hospital from 8 to 12 days with an average stay of 10 days As soon as alcohol was withdrawn and food given, the symptoms promptly disappeared No particular diet, pure protein or otherwise was used, the ordinary hospital diets sufficing to put these patients in good condition

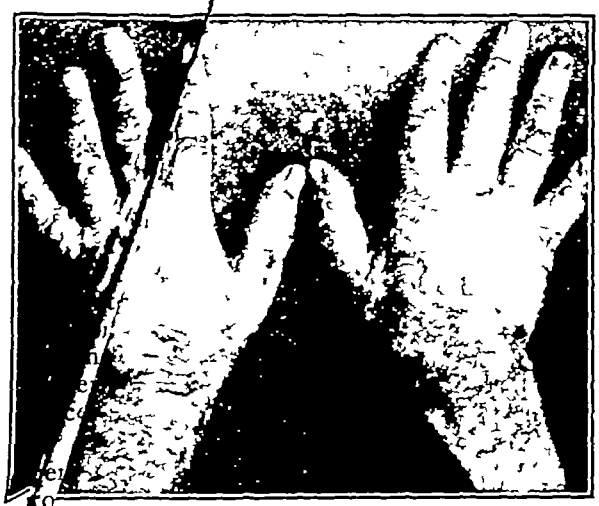
Because of the fact that these cases are only seen during the warmer months, it was decided to test certain of them for the presence of hematoporphyrin in the urine We were able to test only four cases of which one gave a positive reaction

The following case reports are submitted as good examples of the histories of practically all of these cases, the others differing in minor degree only and in nothing essential

Case 1 P R., male, 52, Irish-American, admitted to Bellevue Hospital on June 4th, 1928, suffering from alcohol poisoning and an eruption on his hands The personal history is quite irrelevant, except that he had been addicted to the excessive use of alcoholic drinks for about a year before the onset of his eruption At that time he noticed a redness of the skin on the back of both hands Later he experienced a painful sensation of the hands but no itching

On admission the patient appeared lethargic but not acutely ill The general physical examination revealed nothing unusual The blood pressure was $\frac{140}{75}$

The blood Wassermann test was negative The urine analysis was normal The skin manifestations were as follows



On the dorsal surface of both hands from above the wrists to the phalangial joints, there was a violaceous pigmented eruption, which was symmetrical and sharply marginated with a distinct line of demarcation between the affected dorsal surface and the normal palmar aspect. The skin was dry, somewhat wrinkled and covered by gray scales crusts and marked desquamation No other lesions were noted This patient was placed in bed and given a routine semi-soft hospital diet. His recovery was uneventful Six days after admission, he was discharged as well Only pigmentation was noted on the date of his discharge

Case 2 E M, male, 48, Irish-American, admitted to Bellevue Hospital on June 4th, 1928 Chief complaint on admission was eruption on both hands, with burning sensation of about four weeks' duration

The family history is negative His personal history reveals constipation for the past five years

*Read at the One Hundred and Twenty third Annual Meeting of the Medical Society of the State of New York Section of Dermatology and Syphilology June 5 1929

He had "tetanus due to an infection of the left thumb" three years ago For the past two months he had been drinking excessively and took but little nourishment Physical examination showed a thin male who did not appear acutely ill General physical examination was negative The urine analysis and blood Wassermann tests were also negative His skin exhibited an erythematous

Gloved Eruption almost identical (Pseudo-Pellagra) Characteristic Eruption observed in all these cases

moderately pigmented, rough appearing eruption on the dorsal surfaces of both hands, from the wrists to the phalangial joints The lesions were symmetrical and there was a distinct line of demarcation on both hands No other skin lesions were seen This patient was also placed in bed and a regular semi-soft diet was given In one week he was discharged as entirely well, except for pigmentation on the skin

Comment

These cases are reported because they are typical of a fairly large number of similar ones that have been observed in the Dermatological Clinic of the N Y University during the past seven or eight years It was noticed that from time to time since the advent of prohibition, patients with the skin eruption of pellagra on the hands, but with no other symptoms of this disease, would present themselves at the clinic All of these patients were whiskey drinkers of the type that work just about long enough to earn sufficient money to buy what they could of their favorite beverage The majority of them were Americans of Irish descent (13 out of 21 of our cases) None of them were Jews, thus corroborating the statements of various observers that Pellagra or Pseudo-Pellagra is not found among members of this race

The kind of whiskey used by these patients was necessarily, because of its cheapness, green, unmatured synthetic liquor Often it was undoubtedly nothing more than raw alcohol, denatured with some of the denaturing material removed, plus coloring matter Naturally, while drinking this, they ate little or nothing, and during the warm months, slept out of doors day and night thus being exposed to the action of light It is possible that the ingestion of raw, green, whiskey may render the individual photo-sensitive and thus cause the eruption usually seen

The occasional case of this type, that presents mental symptoms, we believe is due to acute alcoholism and not pellagra. These cases are to be found at times in the alcoholic wards of any large city hospital if looked for

Many of the cases with pellagroid symptoms seen in parts of the South, where moonshine whiskey is used extensively, cases that have generally been called true pellagra, probably come under this classification and are due to the same cause

While it is well known that alcohol is a predisposing factor either directly or as an economic contributing cause in true pellagra, we believe that the above cases should be classed as pseudo-pellagra, rather than as pellagra, for the following reasons

1 They did not present the mental and nervous symptoms of pellagra
2 They did not present the marked diarrhoea
3 The skin eruption in most cases was limited to the hands, only occasionally appearing on the face and then to a very slight extent, and never on the feet

---

THE IMPORTANCE OF SPLANCHNOPTOSIS IN GYNECOLOGY

By HARRY ARANOW, M D, NEW YORK

IN THE early part of my medical career I had the good fortune to become associated with a very good gastro-enterologist in one of the large New York clinics This gave me an opportunity to become intimately acquainted with enteroptosis in its subjective and objective symptoms When a few years later I took up the work of gynecology, I was struck with the frequency with which the symptoms of certain types of gynecological cases resembled those of the splanchnoptotics I had seen at the gastro-enterological clinic A little further study and observation convinced me that these cases were all of the same type and their classification into

*Read before the Bronx County Medical Society Dr Aranow 1928

"stomach" or "gynecological" cases depended upon whether the gastro-intestinal or pelvic symptoms were considered most important by the admission clerk of the clinic In most instances this decision of the admission clerk was rendered final by human psychology In the gastro-enterological clinic the gastro-intestinal symptoms were emphasized, little attention being paid to the pelvic conditions In the gynecological clinic the pelvic symptoms were brought out to the neglect of the gastro-enteric and nervous manifestations Personal experience extending over a period of over twenty years has tended to confirm the observation that a great many gynecological conditions, namely uterine displacements, prolapse of uterus, tubes or ovaries, pelvic varicocele, are often associated conditions of a general splanchnoptosis

If these observations are true, it is self-evident that these cases require the attention of both the gynecologist and the medical man to obtain the best results It is also self-evident that a prolapsus of the uterus, tube or ovary which is part of a general systemic condition of ptosis can not be cured by any local operative procedure This is the message I am trying to convey in this short paper

Etiology

In a brief paper of this character, it is impossible to go into all the theories as to the origin and pathogenesis of either splanchnoptosis or prolapse of the female pelvic organs Permit me to quote a paragraph from the chapter on enteroptosis in Osler's Modern Medicine "Thus the theories regarding the pathogenesis of splanchnoptosis may be broadly placed in three groups 1 The condition is congenital, and is due to an inherent weakness of the tissues which support the abdominal viscera, such factors as clotting, trauma, disease, etc, are not the primary causes, but simply contributory ones, which bring out or accentuate the inherited tendencies 2 The condition is due to pressure of clothing, trauma, weakness of the abdominal walls, various diseases associated with marked loss of strength or weight, various spinal and thoracic diseases, pregnancy and parturition tumors, ascites, in other words, a number of conditions, each of which has as its result the weakening of various visceral supports due in some cases to pressure, in other cases to adhesions, in other cases to trauma, and in still other cases to a marked diminution of the supporting power of the abdominal wall 3 That each of the foregoing may be the primary cause of the condition, in other words, that there may be both an acquired and a congenital form of Splanchnoptosis"

Let me call your attention to the remarkable fact that every one of these theories is also given in text books on *gynecology* as the underlying cause of displacements of the pelvic organs The same theories, i e, congenital weakness of supports, trauma and disease, and a combination of both holds true in both conditions Under the circumstances, the frequent association of splanchnoptosis and displacements of the pelvic organs is to be expected

Frequency

Enteroptosis is frequent in a female patients and still more so in the so-called gynecological patients Dr Einhorn, who sees only cases with digestive disturbance, gives the frequency of ptosis in women as 35% Dr Thompson reports 112 cases in 272 general medical cases 44% In a large series of gynecological dispensary cases which I had gathered some years ago for a paper of this character, about 30% showed distinct signs of splanchnoptosis That means that nearly one out of every three patients coming to the gynecological department of this large hospital dispensary showed physical signs of enteroptosis May I quote again from Osler's *Modern Medicine* "The association of displacements of the pelvic organs with splanchnoptosis is a subject to which little attention has been paid, and yet it is one of extreme importance because retroflexion (bend) of the uterus is a very frequent accompaniment displacement of various abdominal organs Smywick found that of 34 women with splanchnoptosis, 80% had retroversion of the uterus generally in a marked degree, and Smith believes that a majority of patients coming to the gynecologist have splanchnoptosis

Symptoms

In my introductory chapter, I have already mentioned that the general symptoms of splanchnoptosis and of displacement of the pelvic organs are similar, when such symptoms are present As you all knew, these conditions may give no symptoms whatsoever Dr Ashton in his textbook "Practice of Gynecology," lists the symptoms of uterine prolapse under the following headings Backache, Pelvic Symptoms, Rectal Symptoms, Bladder Symptoms, Leukorrhoea, Menstrual Disturbance Digestive Disturbance Nervous Symptoms The characteristic symptoms of splanchnoptosis are backache, headache, indigestion, abdominal and pelvic pains, frequent and often painful micturition, neutasthenia, *plus* the local symptoms attributable to the displacement of the various organs From a comparison of the above lists, one can readily see that the general symptoms of both these conditions are almost identical This important fact is not sufficiently emphasized in text books on surgery and gynecology in spite of occasional sharp reminders by the internist Here is one by Dr Thomas R Brown "It must strike our gynecological brethren that the symptoms which they attribute to retroflection of the uterus bears a striking resemblance to those of splanchnoptosis and this accentuates the fact al-

ready noted that in the vast majority of cases retroposition and retroflection of the uterus are but associated signs of a general splanchnoptosis, and to expect relief by a ventral fixation of the uterus seems chimerical, to say the least" This seems to me a pretty sharp slap at the gynecologist What I cannot understand is why Dr Brown was singling out the gynecologist In our experience the surgeon is just as often to blame for starting on some of these patients on an endless operative career by an operation for chronic appendicitis or floating kidneys, etc I know of the wife of a prominent surgeon who was operated on for chronic appendicitis, floating kidneys, retroversion of the uterus once, retroversion of the uterus a second time To the best of my knowledge, her condition is no better today than it was before the first operation

Diagnosis

The diagnosis of both splanchnoptosis and displacements of the pelvic organs is usually easy With little experience one can spot the tall, thin, narrow-chested, slightly stooped, thin-legged, flat-footed enteroptotic, on the street On the examining table, the long-narrow-chest, the long distance from the ensiform to the umbilicus, the hollow abdomen, suggest ptosis Palpation reveals a poor abdominal wall, often separation of the recti, palpable kidneys, sometimes also liver and spleen The stomach may "splash" some distance below the umbilicus The wall of the large intestine may feel relaxed and toneless, and the contents of the bowel may gurgle under the palpating hand Percussion, after gas distention, will often show a gastroptosis X-Ray makes the diagnosis positive

The diagnosis of displacement of pelvic organs is rarely difficult If the patient is obese, an examination under anaesthesia may be necessary The diagnosis of pelvic varicocele is extremely difficult, and to my mind very uncertain However, what one must keep in mind constantly is the fact that splanchnoptosis and pelvic organ displacements are often associated conditions, and the pelvic descensus may be part of a general ptosis

Treatment

It is not within the scope of this paper to take up the treatment of either pelvic organ displacements, pelvic varicocele, or splanchnoptosis The idea I wish to bring home to you is what is the proper treatment in cases of retroversion of uterus, prolapse of pelvis organs, etc, when the condition is associated with a general enteroptosis?

First The treatment must be both local and general to get satisfactory results The local prolapse or displacement may be treated by posture, tampon, pessary or support The patent must also be given a nutritious, fattening diet, exercise, abdominal massage, and abdominal support. Many a woman may be relieved of her pelvic and abdominal symptoms by a properly fitted abdominal support

Dr Watson of Edinburgh, professor of gynecology and obstetrics at the College of Physicians and Surgeons, in a paper on "The So-Called Ovarian Pains," read before the Eastern Medical Society several days ago made the following statement "It is *amazing* how frequently a woman will be relieved of all her symptoms by a properly fitted abdominal support" He was referring to patients with general and local symptoms caused by tubo-ovarian prolapse and pelvic varicocele

Second and most important It is unscientific and contrary to common sense to expect a cure of a general ptosis by a local suspension operation This does not mean that these cases should never be operated on Occasionally the local disturbance may be so great that an operation may be advisable, but, these highly neurotic patients must not be made to expect more than local relief, and, before operating on a patient of this character, it is the duty of the physician and surgeon to make sure they have recognized the underlying cause of the trouble The symptom-complex of splanchnoptosis is most *complex* indeed It may simulate chronic appendicitis, renal colic, postoperative adhesions, chronic disease of tubes and ovaries, pelvic varicocele, and a long chain of digestive and nervous disturbances In our opinion, this type of cases make up the majority of the unsatisfactory post-operative results Many of these patients are operated on repeatedly without benefit I remember seeing a case that was sent to the hospital for operation for the ninth time

Conclusions

1 Splanchnoptosis is extremely common in patients coming to the gynecologist

2 The underlying causes of enteroptosis and of displacements of the pelvic organs are similar

3 Therefore, the association of pelvic ptosis and general enteroptosis is frequent

4 In a great many cases the pelvic ptosis is simply part of a general ptosis

5 To obtain the best results these patients must be treated both medically and gynecologically (*Medically first*)

6 As a rule operations do not cure this type of cases

ANESTHESIA IN PROSTATECTOMY*

(A Summary of Two Hundred Consecutive Cases)

By WINFIELD SCOTT PUGH, M D, NEW YORK, N Y

It is not our purpose in this brief dissertation to discuss the relative values of suprapubic and perineal prostatectomy as in our opinion the indications for each are well established For the high prostate, projecting well into the bladder, the removal by the suprapubic route is a definite indication A massive gland of the lower type bulging into the rectum is, without doubt best removed by the perineal route, the technic of Young well serving this purpose As to the number of cases coming under each heading we may say that they vary greatly In some of our services we have seldom done a perineal operation, while on the next tour we may have a large percentage of those for attack by the lower route

In this group of cases one hundred were operated on by the suprapubic approach Here we encounter another proposition, namely, as to whether we shall remove the gland by a one or two-stage operation In other words, shall we first drain the bladder by a suprapubic cystotomy, and a little later as the patient's condition warrants, do a secondary removal of the prostate through the cystotomy incision Our alternate procedure is to drain the bladder by an indwelling catheter as long as may be necessary, and then do the cystotomy with a prostatectomy in one stage Opponents of the latter technic tell us patients do not tolerate a urethral catheter, and secondly epididymitis occurs in a high percentage A prolonged period of observation in important European clinics convinced us that the dea of intolerance to a urethral catheter was argely fallacious Certainly 80 per cent had io difficulty in urethral drainage What about epididymitis? Yes, it will occur in a small percentage of cases, but this is most effectively prevented by a bilateral vasectomy as recommended by Goldstein, the writer and a few others It has been claimed that vasectomy does not prevent epididymitis, a large clinic having recently reported four cases occurring in spite of vasoligature We doubt very much the actual severance of continuity of the vas in these instances Let me say right here, this little matter of vasectomy is not such an easy thing as many would have us believe The mere passing of a transfixing needle, opening over where the vas is supposed to be, ligating and cutting something is not necessarily vasectomy One must open the scrotal pouch, definitely isolate the vas, being sure of the structure, ligating and then severing it Remember it must be the vas, a vein or mass of tissue will not suffice We stress this little point because we have made the mistake ourselves and have seen many successful surgeons do the same. In a series of two hundred consecutive cases the following technic has been successfully carried out An area of about two inches in the long axis of each side of the scrotum over the vas is infiltrated with one per cent Tutocain, using a Luer Lock type needle and syringe The cord is then brought up into the wound and the vas carefully isolated It is then resected and about one quarter of an inch removed, the ends ligated and dropped back into its bed The scrotum is sutured with plain catgut so that it does not have to be disturbed and a collodion dressing completes the operation A Pezzar or Malecot self-retaining catheter 18F is now inserted on a mandrin into the bladder and left in place The length of time it is allowed to remain in situ of course depends on the individual case, but in the vast majority one week suffices Remember we always carry out the vasectomy before inserting the catheter

The One State Prostatectomy

In 75 per cent of our cases the removal of the gland was carried out under spinal anesthesia which, with modern technic, is a perfectly safe procedure The spinal technic is now so well known that we shall not discuss it here It is our experience that the remaining 25 per cent of our cases are best operated upon under a strictly local anesthesia This is particularly so in those cases complicated by cardio renal syndrome, as manifested by emphysema, arteriosclerosis, and a myocarditis with hypertensive heart These conditions just named as a matter of fact were the underlying reasons for Laewews pioneer work in local anesthesia of the urinary organs

Aside from the above noted portrayal, one needs must consider also the advanced age of many of these patients and their greatly diminished reserve force Here we have a vitally important factor which must influence us in the choice of anesthesia In perhaps no other class of patients will the baneful effects of a narcosis be so pronounced as in these maladies of the urinary tract in the aged

Are there any factors which might contraindicate the use of local anesthesia in prostatic surgery? Yes, there are two possible negations First, the absence of one skilled in the necessary technic, secondly, the speed mania must be considered, as local anesthesia is posi-

* Read before the Brooklyn Medical Society March 8 1929

tively incompatible with haste No mad dashing and jabbing of needles is permissible, but thoroughness is paramount. It is extremely difficult, in fact well nigh impossible, to anesthetize against pulling and tearing At times your patient will say—"Doctor, I know and feel everything you are doing" What he actually means is that he is conscious of hands and arms of the surgeons on his abdomen Also when a part is put under great tension is cannot be disguised, but you will note he does not complain of pain

Choice of an Anesthetic

Quite a variety of drugs have been introduced into the field of local anesthesia In our present work we are using Tutocain and find it eminently satisfactory This substance is very handy, being put up in tablet form and going into solution very quickly It is much less toxic than cocaine, causes no irritation or tissue injury, is readily sterilized and penetrates rapidly We thus find that all of the essentials of a good anesthetic medium are well covered What about the use of Suprarenin in connection with the anesthetic medium? Those opposed to its use say it causes various nerve disturbances, etc As a matter of fact, our experience which has been considerable convinces us that it makes no difference if you use it or not.

Preoperative Medication

For a number of years it was our custom to use a little morphin and scopolamin as a preliminary, say a sixth of a grain of morphin and 1/250 grain of scopolamin, two doses of these amounts, the first two hours and the last, one hour before operation We now seldom use this (shall we call it preliminary) measure, except in the highly nervous type of patient. That class, however, is not well adapted to local anesthesia

Forty-eight hours before operation the patient is given 30 grains of Sod Bicarb If the gastrointestinal tract is disturbed he is given a two per cent solution of the drug by rectum Twenty-four hours previous to prostatectomy he receives a mild laxative such as a liquid petrolatum, and is allowed to have a peaceful preoperative night

Anesthetic Methods

In surgery of the prostate, aside from spinal technic, we may employ

1 Midline infiltration of the abdomen
2 Abdominal field block
3 Caudal anesthesia
4 Intravesical prostatic infiltration

The first and second must be combined with either three or four

Anesthetic Technic

If we intend to use a caudal anesthesia the patient is placed face downward with a pillow under the pelvis and the sacral hiatus located Note the word "located" If the notch is not quite definite don't butcher up the patient by making countless stabs, as this harpooning gets you nowhere The surgeon who has any intelligence will know at once if he can enter the sacral canal and if there is doubt, abandon it Sacral technic we have described elsewhere If we do a sacral (caudal) shall we combine it with a transsacral? By no means If we stop to study our anatomy—and local anesthesia, requires such knowledge, you will find how superfluous transsacral is I will admit that transsacral has saved many a poor caudal and vice versa Moreover, one must suppose his anesthesist is competent Just one more point regarding sacral before leaving it. You have heard considerable talk about there being subcutaneous swelling if you are not in the sacral canal Perish the thought I have failed in many sacrals, with no evidence of tissue infiltration

Before completion of the sacral anesthesia with one per cent Tutocain, which takes care of the prostate, no matter how high, the patient is turned on his back and we are ready for the abdominal technic We seldom use midline infiltration believing the field block gives us a wider range.

Field Block

This method is well adapted to the suprapubic opening of the bladder as well as to such major technic as resection, deperitonealization of the bladder is recommended by Volcker—the diverticulum methods of Lower and others The transperitoneal resection of Delbru, the removal of tumors high up in the bladder as suggested by McCarthy, Scholl and others are also readily accomplished with field block Even the lower third of the ureter may be approached for the removal of calculi

Illyes, Jones and Labat believe that midline injections somewhat reduce the vitality of the tissue, particularly when placed in contact with septic bladder contents While we have not seen many such incidents, the experience of these distinguished workers is well worthy of note We find three types of field block most commonly employed, their introduction being largely due to the tireless efforts of Hachenbruch, Illyes, and Labat In 25 per cent of our suprapubic prostatectomies one of these three has been employed in every case The more extensive bladder lesions are best done under the wide block as recommended by Illyes and Labat For a simple prostatectomy any one of the three types may be employed Field

block is a typical example of conduction anesthesia In other words, we build a wall of anesthetic fluid which surrounds the nerves in their course and quite thoroughly prevents the passage of impulses

As can be readily seen the abdominal wall is quite an ideal place for this type of anesthesia. We find that much of the innervation occurs from the lateral aspects and is practically in parallel lines

Type one This method as now practiced is very similar to that devised by Hachenbruch Its adaptation to prostatectomy is simple and effective. A superficial wheal is made in the midline of the abdomen an inch and a half or so below the umbilicus A second wheal is made in the midline about an inch above the symphysis pubis A lateral wheal is made at the outer border of each rectus muscle and midway between the pubic and subnavel wheals These punctures now form quite distinctly the points of a rhombus and it is hence at times known as the rhombus method At each wheal a 10 cm needle is inserted and thrust directly downward until the aponeurosis is perforated Injections are then made beneath this fanwise in all directions (see cut) The needle is withdrawn and subcutaneous injections are made in the same manner After completion of the above, about 10 c.c. of the Tutocain is injected through the lower wheal into the space of Retzius

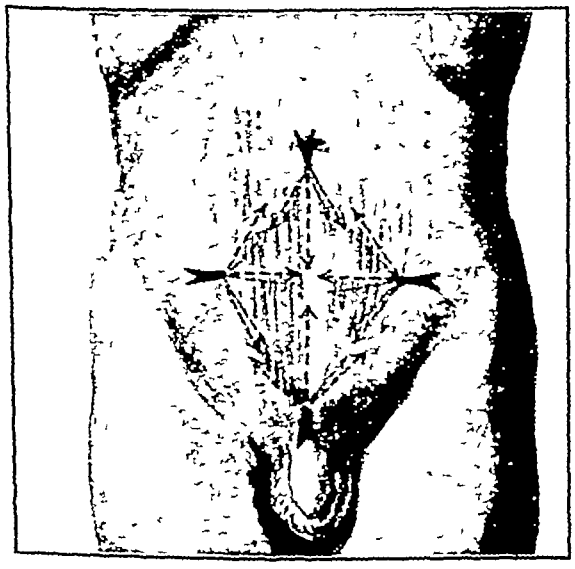


FIGURE 1
Field block type one

Type two This represents the authors modification of the Illyes block. Briefly this is as follows Eight wheals are made in the corium The first, one and a half inches below the umbilicus in the median line A second just above the symphysis pubis Three wheals are then made at the outer border of the rectus muscle. One close to the pubic arch, one just below the umbilical level and third midway between the two At each of these points we penetrate the aponeurosis, and inject a few c c of one per cent Tutocain solution Injections are then made fanwise connecting the

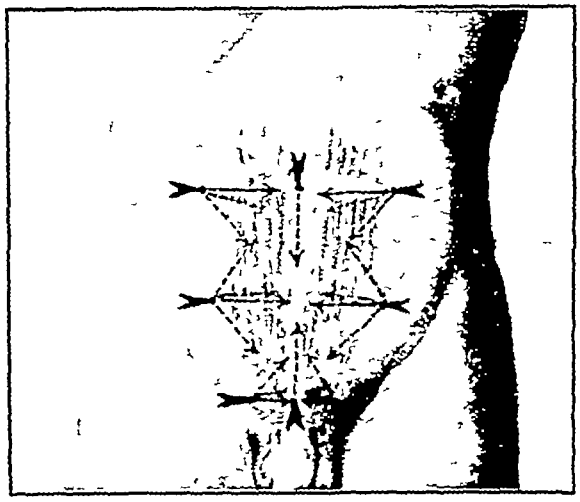

FIGURE 2
Field block type two

points of puncture Through the lateral wheals injections are also made up and down the border of the rectus both intramusculary and subcutaneously Through the lower midline wheal 10 c c of an anesthetic is injected into the space of Retzius

Type three The introduction of this particular form of block is due to Labat. It is both simple and effective. Our procedure in carrying it out is with some slight modification essentially as follows

Wheals are made just above each pubic spine at the outer rectus border Another wheal is placed on the same line just below the navel area, while the third is made midway between the two former Subcutaneous and intramuscular injections are made fanwise all along the lateral border of the rectus as described in block two The space of Retzius is also injected in a somewhat similar manner We have utilized the block technic in almost a thousand cystotomies, both in our own practice and that of other surgeons These vesical approaches we have described fully elsewhere

Before leaving the subject we might say it is not advisable to fill the bladder until the completion of the local anesthesia technic Bladder puncture is regarded as trivial by some, but is still respected by us, after about thirty years of frequent contact Do you ever

REPORT OF CASE OF SYPHILIS IN WHICH DEATH FOLLOWED AFTER THE ADMINISTRATION OF SULPHARSPHENAMINE

By JOHN R. WILLIAMS, M D, and HUGH E PFLUKE, M D, HIGHLAND HOSPITAL, ROCHESTER, N Y

THE testimony of most competent observers is that sulpharsphenamine is a comparatively safe drug and that its use is rarely accompanied by serious reactions No deaths ascribed to its administration have come to our notice The ratio of severe reactions and deaths to various arsenicals is given in the U S Naval Bulletin[1] as follows

Arsphenamin 1 reaction to 436 doses
Sulpharsphenamin None
Neoarsphenamin 1 reaction to 794 doses, with 4 fatal reactions
Trypsarmide None

Many workers have concluded that fatalities have been due to other causes than the toxicity of the arsenical and that many of the so-called reactions after the institution of the treatment are ascribed to insufficient or improper treatment such as too large doses insufficiently spaced Stokes[2] and others[3, 4] have described reactions due to sulpharsphenamine but no mention is made of deaths

The occurrence of jaundice as a complication of the treatment of tertiary syphilis is comparatively rare Stokes discusses this at length and states that the proportion would not exceed 14 cases in 28,000 injections The question whether or not arsphenamine may cause liver degenerative changes is important and is in dispute Zieler states that if the jaundice follows after the development of the rash it must be considered as due to the arsphenamine On the other hand Stokes, Ruedermann and Lemon[5] state that the argument against an arsphenamine etiology is based on the fact that no definite time sequence between the administration of the drug and the incidence of the jaundice can be detected, jaundice often appearing so late that any connection between the two occurrences is merely a matter of speculation There was no constant relation between the total dose of arsphenamine and the severity of the hepatic symptoms which could not be largely explained on the basis of the time intervals in the interim home treatment system of the department Furthermore, arsphenamine had almost no unfavorable effect on those patients who continued it during their jaundice, and resumption of the arsphenamine in 50 per cent of the cases as soon as the jaundice cleared up had no effect in producing relapse They are inclined to the view that an infectious agent, possibly associated with epidemic respiratory infections, is the exciting cause They also suggest that it is in part hematogenous and associated with gastrointestinal lesions They conclude that while arsphenamine may and does act as a predisposing factor in the cases of hepatitis, the exciting cause is probably an as yet unidentified agent

We wish to report a death where it seems probable that the intravenous administration of sulpharsphenamine was a causal factor While the patient had symptoms indicating a gastrointestinal lesion, they were not serious in character and did not interfere with his daily habits or duties There was no history of respiratory infection either with the patient or his family, and no signs were evidenced at the preliminary physical examination Indeed prior to the treatment, careful physical and laboratory studies disclosed no evidence of important visceral lesions other than a low grade duodenal ulcer, and while an active duodenal ulcer was demonstrated at autopsy, there was no evidence that it was an important factor in causing the death A definite history of lues and the positive Wassermann tests formed the basis of the diagnosis which led to the use of the sulpharsphenamine. In all, five doses were given at intervals of one week Within 24 hours after the last administration violent reactions occurred accompanied by a skin eruption and jaundice, followed within a few days by death The details of the case are reported in the following study

The patient was seen for the first time as an office case six weeks prior to his death The details of the history and clinical examinations are as follows Male, age 58 years, divorced, railroad employee Chief Complaint, pain in epigastrium Epigastric distress had been present for more than two years It bore no relation to meals Lasted from a few minutes to an hour Occurred at irregular intervals of days, weeks, or months Always associated with nausea, rarely with vomiting, occasionally aggravated by exercise Previous history without significance except lues at the age of 38 years, which was not thoroughly treated Patient had two healthy children Family history negative

Physical Examination Patient well developed male, no evident illness Skin and mucous membranes normal Mixed gray hair Teeth, eyes, ears, nose, throat, tongue, thryoid all normal Lymph glands not enlarged Moderate sclerosis of large peripheral arteries Lungs clear, heart normal size, sounds regular and clear Except for left inguinal hernia corrected by truss, and a slight localized tenderness in the midepigastrium, the abdomen was normal Pupillary and patellar reflexes equal and active Romberg normal Normal coordination Spine and limbs normal Rectum, prostate and genitals normal

Preliminary urine, blood sugar and non-protein nitrogen examinations were normal Blood was taken for a Wassermann test, a report on which was not available until six days later In the

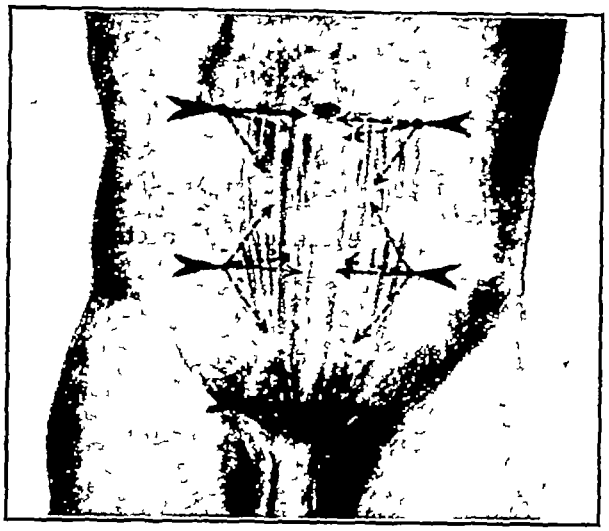

FIGURE 3
Field block type three

strike vessels with the injection needles? Oh, yes, we do and at times we have seen moderate sized hematomas particularly in the supra-aponeurotic layer To date these oozings have never inconvenienced us

THE PROSTATIC APPROACH

The field block being completed our incision through the abdominal wall is made, the peritoneal investment retracted from the bladder and that viscus opened as high as possible The high opening greatly facilitates closure Our prostate is now visualized If you have not as yet given the patient sacral anesthesia, Dr C W Allen of New Orleans, recommends direct prostatic anesthesia by periglandular injections beneath the capsule as follows After the bladder is opened the needle is passed beneath the mucosa on the anterior bladder wall and progressively inserted downward toward the prostate, injecting as it is being advanced When the gland is reached the needle is passed to one side, the solution flowing sub-mucously over it Allen tells us this gives an anesthetic pathway to the field of operation The deep injections are begun at the vesical neck within the anesthetic area and are made from this point backward on each side. Our first is usually made just below the urethra and on each side Further injections are then made around the prostate between the true and the false sheath

We have tried the Allen method a number of times but we are by no means as successful as the originator and our failures have been frequent, so that we have come to rely on the combination of sacral and field block Our finger now outlines the prostate and we then have an assistant elevate the gland by a finger in the rectum Why not put a finger of your other hand in the rectum and do the entire procedure yourself? The answer to this is easy and satisfactory at least to me I know too many instances of prominent surgeons who have forgotten to change the glove after a rectal procedure Being only too human myself I make lots of errors, but would not care to have this one if I can avoid it With a complete anesthesia we proceed to enucleate the prostate by the insertion of our index finger into the urethra, rupturing the anterior commissure This gives us an opening into the prostatic capsule, following which the finger is passed around the line of cleavage from right to left until the adenomatous mass is loose in our hand It is often necessary to cut a few bands of adhesion at various places What about hemorrhage? As a rule it is controlled by hot packs If this will not suffice one of the Pilcher-type bags are employed A drain in the space of Retzius left for 48 hours and a Pezzar catheter in the bladder sewed in place completes the procedure The patient as a rule will begin to void by the urethra in one week if no obstruction has been left. The suprapubic wound should be entirely healed in three weeks

SUMMARY

1 The one-stage method is applicable to 80 per cent of suprapubic prostatectomies

2 Epididymitis will not occur if the vas is properly ligated

3 Local and regional anesthesia is best for those cases not adapted to the subarachnoid technic

7 Pugh, W S Modern Local Anesthesia Technic in Surgery of the Bladder *Atlantic Med J*, May, 1928

The examination of the gross specimens reveals the presence of an old duodenal ulcer, syphilitic aortitis, acute jaundice and hemorrhagic colitis

Microscopic description

Spleen Sections show marked passive hyperemia Sinus endothelium is somewhat swollen No marked reticulo-histiocytic reaction Phagocytic macrophages contain moderate amount of hemosiderin No active erythropagocytosis is noted Malpighian corpuscles are not prominent and lack their central core of undifferentiated mononuclear cells Between the lymphocytes are seen very numerous eosinophiles of microblastic variety

Liver Sections from the liver show rather marked periportal round cell infiltration limited mostly to the bile ducts and bile canaliculi No evidence of diffuse or periportal fibrosis could be detected Kupffer cells are numerous and contain granular yellow pigment while the liver cells show only traces of pigment No Eppinger's biliary thrombi were noted Nothing indicative of acute atrophy or fatty degeneration could be seen

Pancreas Nothing of note except some round cell infiltration in the areas close to the duodenal ulcers

Ulcers Simple plastic type of ulcers with some round cell infiltration but without any features suggestive of specific granulomatous inflammation Specially stained sections did not show the presence of syphilitic spirochetes

Mesenteric Lymph Glands Show diminution of actual lymphoid tissue and replacement of it by the reticulo-histiocytic cells These elements reveal marked hypertrophy and vacuolization of cytoplasm but no visible inclusion of hemosiderin could be noted

Kidneys Show cloudy swelling of the epithelium of the convoluted tubules with marked generalized passive hyperaemia Small areas of arteriosclerotic fibrosis are seen No evidence of active cellular inflammatory reaction or toxic destructive changes are noted

Aorta Shows round cell infiltration in the adventitia with moderate sclerosis

Lungs Show marked emphysema with the presence of numerous heart failure cells

The cause of death in this case is not clear It is suggested that since no definite anatomical changes were found in any part of the biliary tract, that the jaundice observed was due to a blocking of the reticulo-endothelial system, with the result that bilirubin accumulated in the blood and tissues A direct van denBergh reaction which was obtained does not controvert such interpretation, in view of van denBergh's observation of direct reaction in cases where no anatomical changes could account for any obstruction and where the direct reaction was probably due to heart failure with impairment of cellular oxidation which interfered with the transformation of bilirubin into biliverdin It is known also that the active treatment sometimes stirs up latent syphilis, Herxheimer reaction, and the mobilized spirochetes together with the arsenical preparation administered may block the reticulo-endothelial system and thereby produce jaundice It is possible that therein lies the explanation of the death in this case, and that the kind of arsenical administered was immaterial

THE WORK OF THE GRIEVANCE COMMITTEE

By HAROLD RYPINS, M.D., ALBANY, N Y

A summary by the Executive Secretary of the Grievance Committee New York State Department of Education

THREE complementary factors are necessary to maintain a high standard of medical practice first, high educational standards for licensure, second, the elimination of illegal practice, and third, the discipline of licensed physicians who have drifted from the straight and narrow path of professional rectitude The amended medical practice act provides all three of these functions, the third of which is the sole function of the Grievance Committee

This report deals solely with the third function, that of the Grievance Committee, but it is obvious that the business of disciplining licensed practitioners would be farcical were it not complemented by both high requirements for licensure and adequate prosecution of illegal practitioners of medicine

Prior to the passage of the Webb-Loomis bill, charges against licensed physicians were heard by committees of the Board of Medical Examiners, whose findings were acted upon by the Board of Regents Apart from the fact that the Board of Medical Examiners had other heavy duties as its primary function, this arrangement was not satisfactory for the reason that the public never brought its complaints against physicians before that Board, so that its work was practically limited to the cases of physicians convicted of felonies, all charges being initiated by the Department of Education

meantime a provisional diagnosis of gastrointestinal ulcer was made and dietary and alkali therapy begun The Wassermann report was as follows Alcoholic antigen 4 plus, cholesterin antigen 4 plus, Kahn test 3 plus A confirmatory test was immediately made with similar results Neither the gastrointestinal symptoms nor the pain were satisfactorily relieved and vascular syphilis was considered as a factor The treatment of the lues was then deemed advisable Sulpharsphenamine 0 6 gram dissolved in 10 cc of freshly distilled water was given intravenously and yellow oxide of mercury in half grain doses by mouth twice daily was ordered After 7 days a second dose of sulpharsphenamine 0 9 grams was given in the same manner This dose was repeated at intervals of one week until the patient had four doses Up to this point the patient had been feeling well and seemed to be benefited by the treatment After the fourth dose the patient developed an extensive maculopapular eruption over the extensor surfaces of the arms and about the ankles This rapidly spread over the body, becoming confluent and dusky red in color The face was not involved A slight pruritus was associated with the rash and a feeling of malaise became evident Mouth temperature at this time was 99 degrees Fahrenheit There was a marked tenderness of the feet Suspecting a Herxheimer reaction, after an interval of one week a fifth dose 0 9 gram was given, which seemed to greatly aggravate the symptoms The patient was then given sodium thiosulphate intravenously beginning with 0 3 gram and increasing 0 1 gram daily up to 1 gram For the first three days of this treatment the rash continued to increase and then suddenly temporarily subsided The feet continued to be very tender and the patient was unable to walk One week later the patient became more acutely ill, a profound degree of jaundice developed and the patient was sent to the hospital where as above stated he died 48 hours after admission On the day of death the blood sugar was 83 mg , non-protein nitrogen 70 6 mg , icteric index 60, hemoglobin 88 per cent, red blood cells 4,600,000, white cells, 16,900, van den Bergh test immediate direct and positive Urine contained a few casts and a trace of albumen, otherwise was normal Rectal temperature was constantly around 104 degrees Fahrenheit, pulse from 110 to 120, respirations from 20 to 35

A post mortem examination was made by Dr N W Popoff with the following result

External The body is that of a well developed, rather stout man with marked icteric discoloration of the skin and visible mucous membranes The face and lower portion of the legs are covered with an eruption of the papular type The pupils are slightly contracted The nose, mouth, ears and genitalia are negative Considerable rigor mortis is present

Abdominal Cavity The abdominal cavity contains a normal amount of yellowish fluid Organs, examined in situ, show the following The spleen is soft, large and cyanotic The liver is firm, enlarged and congested The gall-bladder is distended and filled with bile No evidence of stones or any extrahepatic obstruction is present The pancreas is soft and does not show any changes of special note The stomach appears normal The small and large intestines show no gross changes The kidneys show slight lobulation of the arteriosclerotic type

Thoracic Cavity The heart is in normal position and is of normal size The lungs appear markedly congested and edematous, otherwise they are negative

Spleen and Liver The spleen on cutting appears soft and mushy and weighs 350 grams The liver weighs 2,385 grams Its cut surface gives the appearance of nutmeg liver with congestion.

Gall-Bladder On opening the gall-bladder and extrahepatic ducts down to the ampulla of Vater no obstruction is found and the probe can be inserted without any difficulty into the duodenum

Stomach The stomach on opening shows marked hemorrhagic congestion of the mucosa

Duodenum and Intestines In the duodenum on opening are found close to the pylorus two healed ulcers and one fresh ulcer about two inches above the ampulla of Vater The mucous membrane in this region appears congested and connective tissue overgrowth in the submucous portions is noted The serous coat in the region of the ulcers mentioned shows some adhesions but no evidence of perforation is found The small intestines down to the cecum do not show changes of note The ascending and transverse parts of the colon appear hemorrhagic and congested

Kidneys The kidneys each weigh approximately 350 grams The capsule strips readily and the outer surface appears reddish gray On cutting the parenchyma appears markedly congested and the arteriosclerotic scarring of the tissue is noted

Urinary Bladder No changes of note are found in the bladder

Heart and Aorta About 150 cc of yellow fluid is found in the pericardial cavity The heart on opening does not show any changes on the right side except that the right ventricle has a very thin wall The left ventricle is normal The papillary muscles of the left ventricle are thickened and several sclerotic patches are found on the bicuspid and aortic valves In the abdominal part of the aorta above the celiac axis many arteriosclerotic patches with ulceration are found and the longitudinal rugae usually associated with syphilis are noted

Lungs The lungs weigh 1,125 grams The cut surface appears very edematous, but no evidence of active pulmonitis, infarcts or embolism are found

the fact did not justify civil prosecution, and so far as can be determined, none of them have ever reached the civil courts What might have become of these charges had they been submitted to some legal shyster can only be left to unpleasant conjecture

By far the largest number of cases were dismissed after an informal hearing before a sub-committee In these informal hearings no written charges are preferred against the physician and none of the witnesses are placed under oath However, a written record is kept of all the testimony The complainant and the accused physician are each permitted to give his side of the story, after which the sub-committee determines whether or not the facts warrant a formal trial Of 41 cases, 34 were dismissed after informal hearings, apparently to the satisfaction of both of the contending parties One case was dismissed by the whole Grievance Committee, where the sub-committee had deemed a final hearing necessary, making a total of 50 out of 56 cases against licensed physicians which were disposed of without reference to the Board of Regents, legal costs to the complainant and defendant, or unpleasant newspaper notoriety

tice, and it has deliberately pursued the policy of saving the brand from the burning by moderate punishment wherever such a course appears practicable

These cases do not include the cases in which a physician has been convicted of a felony, where the statute does not require a hearing before the Grievance Committee, but the physician is disciplined directly by the Board of Regents The license of one physician convicted of a felony has been revoked during the year 1928-29

Types of Cases, Ambulance Chasing —At the request of the Committee of the Bar of the County of Kings, the Department of Education investigated charges of ambulance chasing against 13 physicians, connected with Kings County hospitals, which were presented to the Grievance Committee for consideration With the exception of one case, where the question of deliberate falsification of medical records is involved, and which is still pending, the investigation showed that all of the men involved were internes or very young practitioners, who had for the sake of relatively small sums of money become "runners" for an unscrupulous ring which was exploiting compensation cases There was no evidence that

CHART I Character of charges against physicians, showing disposition of cases

	Complaints	Dismissed			Forwarded To Regents			Pending
		By Secretary	After Informal Hearing	After Hearing	For Revocation	For Suspension	For Censure

Fig I	61	50			6			5

Of the 6 remaining cases, 2 have been censured and reprimanded by the Board of Regents upon the recommendation of the Grievance Committee 2 cases are pending before the Board of Regents with a recommendation for suspension of practice, and only 1 has been recommended for revocation These disciplines are on the whole much less severe than those formerly given by the Board of Regents after hearings by the Board of Medical Examiners The Grievance Committee is very sensible of the severity of taking away from a physician his only means of livelihood, thereby forcing him into poverty or illegal practice these physicians had violated any statute or committed fraud and deceit in their practice, but they had more or less unwittingly connived in conduct which was highly unprofessional In view of all these facts and the fact that all of these physicians were just starting on their professional careers, the Grievance Committee let them off with a very strict warning and reprimand

There is no doubt that the effect of this reprimand was very telling, and that these young physicians were made to realize very acutely the advisability of developing their practice upon ethical lines Their records are of course in the

Under the present law, the Board of Medical Examiners is charged solely with the examination of candidates for medical licensure, and the newly constituted Grievance Committee has sole jurisdiction to hear charges against licensed practitioners A casual analysis of the year's activities of the Grievance Committee is sufficient to show that this is a very arduous duty

Constitution of the Grievance Committee — The Grievance Committee is composed of ten practicing physicians, four of whom are nominated by the Medical Society of the State of New York, two by the Homeopathic Medical Society of the State of New York, one by the New York Osteopathic Society, and three by the Board of Regents Each member serves for a term of five years All the hearings are held before sub-committees of three members, the vast majority of the work naturally falling upon the sub-committee in New York City, composed of Dr Orrin Sage Wightman, chairman, Dr Moses Keschner, and Dr Roy Upham The Committee is particularly fortunate in having the legal services of Sol Ullman, Esq and George Fleckenstein, Esq, deputy assistant attorneys general, who act as counsel The expenses of counsel and the cost of the expert court stenographers required for preparing the necessary legal records are paid out of the two-dollar annual registration fees, the members of the Grievance Committee and the Executive Secretary serve without compensation

Advantages of a Grievance Committee —The advantages of a Grievance Committee, composed of ten prominent physicians, may be summarized as follows

1 A physician is tried in the first instance by a court of his peers, who appreciate the particular tribulations and embarrassments, misunderstandings and difficulties common to medical practice

2 A court of physicians can readily understand the inevitable technicalities arising in any medical litigation, which would naturally confuse and trouble a lay court

3 A body of representative medical practitioners is best equipped to pass upon all questions of proper professional conduct

4 The public has confidence in the just determinations of a professional body such as the Grievance Committee in matters involving medical practice

5 The Board of Regents and the higher courts, who have final jurisdiction in all matters pertaining to the revocation of medical licenses, have confidence in such a body and their final determinations will be heavily influenced by the judgment of the Grievance Committee

The work of the Grievance Committee is of benefit both to the public and to the licensed practitioner of medicine For the public the Grievance Committee serves as a court to discipline and sometimes to revoke the licenses of physicians whose professional conduct is a menace to the public, as well as to arbitrate disputes between the public and physicians without the expenses attending an ordinary legal proceeding

The benefit to the medical profession is even greater In the first place, by voluntarily keeping the medical profession clean, the Grievance Committee has undoubtedly raised medicine's prestige and increased the public's respect for the profession's reputation and honor Secondly, it has quietly and efficiently disposed of a large number of unfounded claims against physicians, most of which would have found their way into a civil court, creating not only unnecessary expense, but highly unpleasant publicity for the accused physician, thirdly, it has restarted a number of ambitious but ill-advised young practitioners upon the road of professional ethics, fourth, its existence serves as a constant warning to the weaker members of the profession that misconduct will receive prompt discipline and is too risky to be profitable, and lastly, it has eliminated from practice those few disreputable members whose conduct lowers the reputation of the medical profession in the eyes of the public

Result of the Year's Activities —An analysis of the Grievance Committee's activities for the year 1928-29 is given in Chart I which shows the extent and variety of the work which has been accomplished In all, 61 complaints were received against licensed physicians, of which 5 are still pending, and 56 were completed The complaints include ambulance chasing, 13, improper advertising, 10, attempted abortion, 7, malpractice, 6, aiding illegal practitioners, 5, fraud and deceit in practice, 4, unethical conduct, 1, narcotic violations, 1, miscellaneous, 14 The miscellaneous charges include forgery, bastardy, incompetence, immorality, failure to pay debts, and overcharging Chart II shows the final disposition of the 56 cases

It is apparent that in practice the Grievance Committee operates as a series of sieves, disposing of charges against licensed physicians where the evidence does not warrant further action It also prepares the record and the findings of fact in the few cases where the Grievance Committee determines that discipline by the Board of Regents is indicated Thus, of the 56 cases completed for the year 1928-29, 50 were disposed of by the Grievance Committee, without reaching the Board of Regents Fifteen cases were disposed of by the Executive Secretary on the grounds that the complainant had not submitted sufficient evidence to justify a trial or that the nature of the charges submitted did not fall within the purview of the Grievance Committee These include numerous charges of malpractice and negligence, which must of course be tried in a civil court In most of these cases the facts submitted warranted the Secretary's informing the complainant that

calling in consultation in a serious obstetrical complication a practitioner with no more experience than himself, and thirdly, in performing a major surgical operation for which he had neither the experience nor the training After a vigorous warning, the sub-committee dismissed charges, but there is no doubt that Dr A B returned to practice a sadder but wiser man, and there is little likelihood that he will ever be guilty of any future professional misconduct

As a result of this case the hospital superintendent is taking up with the hospital association the necessity of checking up on all of the credentials of all applicants for internships

Malpractice —There were several charges against physicians in cases where children had died from diphtheria, and in which the parents' ignorance of the situation led them to believe that death resulted from the physician's incompetence Patient and courteous explanations of these situations by members of the Grievance Committee invariably resulted in a proper understanding of the situation Similar disposition was made of charges that physicians had failed to respond to emergency calls On the other hand, at least one complaint showed upon investigation that a physician had apparently practiced fraud and deceit upon an innocent patient, and this case is held for formal trial in the near future

Summary —An analysis of the work of the Grievance Committee for the year 1928-29 shows that it has been of benefit both to the public and to the medical profession, that it has quietly and intelligently disposed of unfounded charges against practicing physicians, that it is leading erring practitioners to the straight and narrow path, that it is eliminating improper physicians from the practice of medicine, and that it is increasing the public's regard for the medical profession's integrity and ethical standards

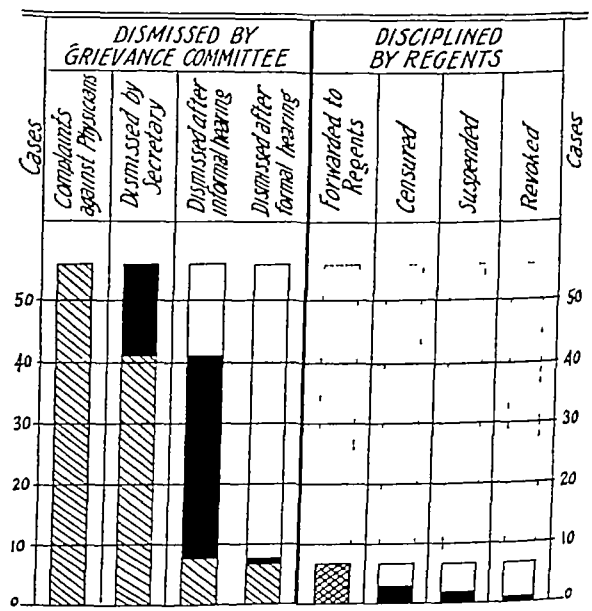
files of the Grievance Committee and they realize that any second offense will not pass unpunished This action of the Grievance Committee not only set these young physicians aright, but it served notice upon the interested profession at large that ambulance chasing and similar charges would not be tolerated in the future

Similar charges involving more serious infractions on the part of 8 Manhattan physicians have been investigated by the Citizens' Committee Against Fraudulent Claims, and the Medical Society of the County of New York These cases will be tried formally before the Grievance Committee in the fall

Informal conferences between members of the attending staff of several municipal hospitals resulted in the introduction of an ethical system for the payment of physicians' services in legal duties, compensation cases occurring in municipal hospitals

Improper Advertising —Of 10 cases of improper advertising, one was dismissed by the Executive Secretary as unfounded and one was censured by the Board of Regents The remaining 8 cases were made up of charges against physicians most of whom were foreigners who indulged in either misleading or unethical advertising After informal hearings, these physicians all agreed either to discontinue all advertising, or to submit their future advertising to the Grievance Committee for censuring This is a field which will doubtless occupy the Grievance Committee for some time to come, and its activities in this field are bearing fruitful results

Aiding Illegal Practitioners —There were 5 charges of licensed physicians aiding and abetting illegal practitioners Two of these cases are still pending and 3 were dismissed after informal hearing and warning by the Committee. The value of the Grievance Committee is particularly well illustrated by the following case



Dr A B graduated from one of the leading New York medical colleges three years ago During his internship at a leading municipal hospital he became friendly with another interne, Dr X Y , who had previously served an internship in another hospital in New York City After practicing two years in Brooklyn, Dr A B decided to move his office to Manhattan, when he chanced upon Dr X Y , whereupon the two opened offices together

Shortly thereafter, Dr X Y had a difficult confinement case and called Dr A B into consultation Dr A B , after consultation with a third physician, who had also been a fellow-interne, decided that the case required a Cesarean section He thereupon removed the patient to a small sanatorium, performed the Cesarean section, and delivered a living child The patient recovered from the operation but died within ten days from sepsis following endometritis.

Upon investigation, the health authorities discovered that Dr X Y was not a graduate physician, but when the Department of Education attempted to arrest him for the illegal practice of medicine, he fled the State Dr A B was thereupon brought before the Grievance Committee on the charge of having aided and abetted an illegal practitioner in the practice of medicine, resulting in the death of a patient, and in the filing of a falsified death certificate

Had this case come before a criminal court, there is little doubt that this physician's reputation would have been wrecked However, he appeared before the Grievance Committee without counsel, but accompanied by the superintendent of the municipal hospital in which he had met Dr X Y while serving as an interne The hospital

CHART II *Summary, Showing Disposition of Cases*

superintendent stated that Dr X Y had been appointed as an interne in his hospital on the submission of evidence that he had previously held a similar position in a reputable New York City hospital, so that his medical credentials were never questioned Dr A B therefore naturally assumed that Dr X Y was a physician owing to the mistake of the hospital in which they were internes The superintendent vouched for the professional integrity of Dr A B during both his internship and his subsequent practice The death certificate filed by Dr A B had not been falsified as it showed endometritis as a contributing cause of death

It was pointed out in no uncertain terms to Dr A B that he had made three serious mistakes in judgment, first, in practicing in the same office with an individual concerning whose professional qualifications he had no knowledge, second, in

PERIODIC HEALTH EXAMINATION CAMPAIGN

The physicians in New York State are developing a growing consciousness of their duty to the public,—to give medical service, in all forms, to all classes of people Individual physicians are exceedingly conscientious in giving curative treatments in private practice and in hospitals Doctors are also developing a conscientious sense of duty to give equally efficient treatment along preventive lines But physicians say that people do not appreciate preventive medicine, and the people retort that the average doctor says "Forget your trouble and come back if it gets worse"

The problem before the medical profession is to inoculate a sense of individual responsibility for the practice of preventive medicine, in every doctor and every lay person,—the doctor to give the advice and the layman to seek it

The problem has been studied by special committees of the larger medical societies, and standard methods of its solution have been developed under the name of the Periodic Health Examination The Medical Society of the County of New York sponsored a series of lectures on the periodic health examination in 1925, and published them in a book of 185 pages The Kings County Medical Society also promoted the examinations by a series of lectures and demonstrations These two societies have continued their activities with the cooperation of some of the leading lay organizations engaged in public health work

The Medical Society of the State of New York has also taken up the movement, and on June 3, 1929 the House of Delegates passed the following resolution which was introduced by the delegates from Bronx County

> *Resolved,* That a special committee be appointed by the President whose duty it shall be to popularize periodic health examinations, and that a week be set apart to be known as health week to initiate this campaign

In accordance with that resolution, the following special committee was appointed

Dr C Ward Crampton, Chairman, New York
Dr George B Stanwix, Yonkers
Dr Luzerne Coville, Ithaca
Dr Charles C Trembley, Saranac Lake
Dr W W Britt, Tonawanda
Dr Joseph P Garen, Olean

This committee will hold a formal meeting in Saratoga Springs on Friday September 20 in connection with the annual meeting of the Fourth District Branch, but the Chairman has done an immense amount of preliminary work and has cooperated with the special committees of New York City

The work in New York City has been developed by all its five county medical societies to the stage of the formation of a Greater New York Committee on Periodic Health Examination This committee used a full page of the Magazine Section of the *New York Times* of Sunday, August 18, 1929, for an educational advertisement calling attention to the principles underlying periodic health examination It answered such questions as the following

What organizations are promoting public health examinations?

What is the prevalence of insidious diseases that should be detected in their earliest stages?

What health agencies are cooperating with the medical profession in promoting periodic health examinations?

What is the distinction between the "silent" and the "speaking" forms of disease?

What is the difference between the periodic health examination and the medical examination that has usually been done in the past?

This public announcement is the first step taken by the five county medical societies of Greater New York toward popularizing periodic health examinations The part to be taken by the Medical Society of the State of New York will be determined largely at the September meeting of the special committee An essential part of the work of that committee will be to popularize public health examinations in the minds of physicians themselves

The advertisement is an excellent example of the education of the people which must accompany the efforts of the medical profession It was paid for by four of the largest lay health organizations in New York City The New York Tuberculosis and Health Association, The Milbank Memorial Fund, The Life Extension Institute, Inc., and The Metropolitan Life Insurance Company This was in accordance with the principle that popular medical education is one of the great functions of lay health organizations as set forth in the agreements made in connection with the Cattaraugus County controversy (See this Journal December 1, 1928, page 1433)

Physicians will attend to the education of their own patients in methods of making periodic health examinations, but it is the peculiar work of the large health organizations to influence patients to go to the doctors for the examinations

With the appointment of this new committee, the Medical Society of the State of New York has taken a well-considered and an apparently epoch-making step forward

FALL ACTIVITIES

With the Fall there comes an enhanced activity of the Medical Society of the State of New York Much advance is expected in the work of the various committees, whose chairmen and members labor earnestly for the advancement of medicine and the benefit of the individual doctors Each committee has its own problems which it must solve for the benefit of not only the individual physicians, but also the public at large

Medicine in its modern form has changed much in the last few years, and so has the physician, but the ideals of the profession remain the same As the Society has met its responsibilities in years past, so it will meet the newer problems with vigor, and will decide them promptly for the good of its constituents, the doctor and the patient, and the people

JAMES N VANDER VEER

MEDICAL PROGRESS

Problems in Nutrition.—*Professor I Abelin* of Berne discusses the influence of the thyroid on nutrition, and the significance of fat in carbohydrate metabolism Under the first head he takes up successively the metabolism of fat, of casein, and of mineral matter (phosphates and calcium salts) and the influence of vitamins Having given the status to date of research into these subjects, he concludes as follows It is difficult to find another substance which can produce such basic and permanent modifications of nutrition as the thyroid hormone Research into various animal species also shows that the picture of hyperthyreosis is superior in character and limitation to almost any other known physiological condition Nevertheless it is quite possible to modify this action in either direction The most important of these factors is the kind of nourishment. The addition of special food stuffs to the usual regimen is sufficient for this purpose and there are numerous kinds to be considered, so that we can hardly think of an isolated action of the hormone In the therapy of the future these modifications of the diet must be borne in mind The author's data are all based on experiments with small laboratory animals, so that they can hardly be applied with certainty to man Thus in hyperthyreosis the liver function suffers, but if substances rich in vitamin B be used for diet this result is prevented A diet rich in casein has the same antagonistic property In regard to the influence of fat on the carbohydrate metabolism, as studied especially in the formation of glycogen, the author concludes from his experiment that the amount of glycogen formed and a large portion of the total carbohydrate metabolism are dependent not only upon the kind and amount of the ingested carbohydrate but also upon the momentary situation of the fat metabolism The carbohydrate and fat exert a check upon each other, the carbohydrates protecting the organism against acetonuria while the fat in turn exerts a like protective role—*Klinische Wochenschrift,* May 28, 1929

The Problem of Otosclerosis—Macleod Yearsley states that heretofore attention has been concentrated almost entirely upon the changes found in the labyrinthine capsule in otosclerosis, leaving the cerebral auditory centers unheeded, that is, the organ *by* which we hear has been neglected for that *which* we hear Recent work upon chronic intestinal intoxication throws a flood of light upon the causation and course of otosclerosis McDonagh's investigations show the blood changes resulting from the chemical poisons manufactured in the intestine There is a precipitation of the protein particles of the plasma in the pericapillary lymphatics in the temporo-sphenoidal lobes, which, by taking electrons from the neurones would cause the cortical cells to undergo degeneration It is, therefore, in an examination of the cerebral cortex of the temporo-sphenoidal lobes that elucidation of otosclerosis will be found In support of this hypothesis Yearsley points to the fact that every case of otosclerosis exhibits one or more of the cardinal signs of familial chronic intestinal intoxication, together with a marked degree of malcoordination Tinnitus, usually hissing in character, frequently precedes deafness, and is highly suggestive of a central irritation It is significant that the tinnitus is not seldom satisfactorily relieved by efficient treatment of the toxemia The foregoing remarks indicate that treatment directed less at local than at general conditions offers greater promise of success as a means of prevention The general treatment indicated consists in disinfecting the colon, preventing reinfection by careful revision of the diet, and the use of vaccines made from the intestinal flora This treatment must be patiently persevered in for one or possibly two years At the same time local treatment should not be neglected The electrophonoid method of Zund-Burguet has given the writer good results in several cases Diathermy also may be helpful Seven illustrative cases are cited in which treatment of chronic intestinal intoxication was followed by marked improvement in the hearing and in the general condition of the patients—*The Practitioner,* June, 1929, cxxii, 6

Roentgen Therapy of Pertussis—Ernest Charles Samuel states that, although pertussis was treated by Roentgen therapy as far back as 1907, and its use has slowly increased, it is by no means employed to the extent it deserves In a series of 850 cases in Massachusetts, in which the Roentgen rays were used uniformly, the mortality was 0 3 per cent as against a general mortality for the State of 6 4 per cent for the same year The author's method of treatment is to give exposures at intervals of three to seven days, depending upon the severity of the case The average number of treatments required is

LEADING IN HEALTH PROGRAMS

Commenting on the editorial in the July 15th issue of this JOURNAL, entitled "Doctors and Health Programs," the July-August issue of the *Nassau Medical News,* the monthly organ of the Medical Society of the County of Nassau, says

"It was the recognition of the truth of these statements and the realization of the possibility for service which prompted the Medical Society of the County of Nassau to open its own headquarters, employ full-time representatives, institute as its mouthpiece the *Nassau Medical News,* and make possible the increased activities of the several committees having to do with our relations with the public and with the other health organizations of the county

"The physicians of Nassau County are no longer isolationists, they are organized to carry health programs to the people, they are in position to meet their responsibilities for leadership in these programs And the lay organizations of the county, recognizing these facts, are coming to the physicians more and more for advice, guidance, and assistance The physicians are not being asked merely to 'endorse' a program after it has been completed, but are actively participating in the formation of those programs as well as in their execution

"The Diphtheria Prevention Commission, now in the process of formation, is merely an example of the work which can be done by the 'peaceful cooperation' spoken of above Hand in hand, with mutual respect and confidence, the physicians and the lay organizations in Nassau County, presenting a united front to face our many common problems, constitute a power and force which should make Nassau County one of the banner counties of the State in matters of public health and preventive medicine"

This quotation is concrete evidence of the performance of their civic duties by practising physicians through the County Medical Society Note the suggested contrast between an endorsement of a program after it has been completed and a leadership in the formation and execution of that program

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Bureau of Information — Twenty-five years ago in the days before the amalgamation of the two State Medical organizations, the New York State Medical Association ran a Bureau of Information, concerning which the Journal for September 1904 says

"Many times since its incipiency, we have been tempted to close our Bureau of Information Recently, however, physicians in this State, and not a few in neighboring States, have awakened to the advantages we offer them.

"As an example of what we do, Dr A, living in Manhattan, wants a "Sayre's Extension Tripod", he needs it for use to-morrow morning He telephones 2810 Madison Square, and we report to him within an hour the houses which have them in stock and the prices they ask

"Dr B, living 250 miles from New York City, wishes a sterilizer immediately, for a particular purpose Instead of communicating with a dozen firms, and examining their catalogues for what he needs, Dr B, writes a description to us, with details as to an approximate price he is willing to pay, and the day he wishes it delivered, and we attend to everything else

"Where do our profits come from? From a percentage on the sales? Oh, no, we are not doing this work for a few dollars in cash, but for a position of power between the physicians of the New York State and the merchants who can supply their wants

"The advantages to the Journal and to The New York State Medical Association itself, which may be had by the members of this Association, making every use of their Bureau of Information, are inestimable It took a long time to make our members realize the personal profit, in money, and time, which we are ready to offer

"Now, thank you, we are doing very well Advice and prices furnished on all things, professional, household or personal, desired by our members"

the pioneer work of Sauerbruch and others in this direction and to the contradiction subsisting between the views of this surgeon and Balint. One insists that a local acidosis constitutes an optimum for healing, the other has it that an alkalosis is best for this purpose The author cites a case which may throw light on this difference of opinion The patient was a freak who as a result of training could control most of the smooth muscles of his body —could dilate and contract his pupils at will, give himself gooseskin, accelerate or slow the pulse, displace the heart, etc This patient happened to sustain a röntgen burn on his back, 23 cm by 11 cm in extent, which had persisted unchanged for 15 years as a raw surface There was a purulent discharge with a fetid odor, and the lesion had resisted every attempt to heal it About a year ago signs of stenosis of the esophagus appeared, due presumably to cancer in situ As a result the patient became very thin from undernourishment, but, striking to relate, the ulcer on the back healed under the author's eyes in the space of 8 days The patient, however, died from his malignant growth The patient in his fasting state had naturally developed an acidosis and the author adds this case to those already described by Sauerbruch One must not generalize too hastily, however, for in diabetic acidosis some other factor must be at work to account for the difficult healing, the increase of blood sugar being sufficient for the purpose. The experience of Balint in favor of an alkalosis optimum for healing also argues for the likelihood that there are a number of factors which may make or mar healing and that each should be considered separately —*Klinische Wochenschrift*, June 4, 1929

Abdominal Pain in Children.—H W Carson discusses some of the difficulties of diagnosing abdominal disorders in children, because of the diversity of the references of pain, the inability of the infant to explain matters, and the liability to attacks of colic due to unsuitable feeding The stomach, liver, and pancreas may be excluded as causes of abdominal pain in early life Intestinal indigestion is the cause of the majority of abdominal pains and readily yields to simple treatment. Severe summer diarrhea accompanied by tympanites may be difficult to differentiate from a surgical disorder In Henoch's purpura, which is characterized by gastric crises and hemorrhages from the mucous membranes, it is difficult to exclude intussusception or other acute abdominal emergencies If the blood shows diminished platelets, this is a help in diagnosis Surgical disorders causing abdominal pain in children may be classified as *inflammatory*, including appendicitis and the various types of peritonitis, and *peristalsis*, including pyloric obstruction, intussusception, and obstructions of various kinds An acute abdominal condition in a child is more likely to be appendicitis than anything else It is a question whether chronic appendicitis occurs in children at all, but there is a condition of hydrops, due to stricture of the appendicular lumen, following an acute attack of appendicitis which has not been recognized. In children abdominal rigidity cannot be depended upon as a diagnostic sign to the extent that it can be in adults The diagnosis of appendicitis should not be made until pneumonia and pleurisy have been excluded Of the acute peritonitis cases in children those due to appendicitis are the most common Acute tuberculous peritonitis and acute pneumococcal peritonitis are occasionally seen In each case the pain is generalized, but the temperature is higher than in appendicular peritonitis Instances of intestinal obstruction in children are practically limited to intussusception and adhesions in acute or tuberculous peritonitis Pain is a most valuable sign in those cases of post-operative ileus following acute peritonitis, it is a direct call for operation, without waiting for vomiting and distention which soon follow Among the causes of chronic abdominal pain is irregular peristalsis, which may be due to many external stimuli, most commonly to dietetic indiscretions The writer has never seen a child with intestinal stasis due to Lane's kink, Jackson's membrane, or enteroptosis Enlarged tuberculous mesenteric glands are a common cause of abdominal pain They are difficult to diagnose unless they have reached the stage of calcification, when they may be detected by the x-rays, and then they may be mistaken for ureteral calculi In these cases the pain is usually near the umbilicus, appears suddenly, passes off as quickly as it comes, and may not return for a week or two —*Canadian Medical Association Journal*, June, 1929, xx, 6

Role of the Gingival Tonsil in the Pathogeny of Pyorrhea.—Rene Vincent, a stomatologist of Paris, states that all authors admit the role of the absorption of the maxillary in the genesis of pyorrhea This makes it possible to understand something of pyorrhea in the aged, in the tabetic, and sufferers from various endocrino-sympathetic maladies, but is insufficient to account for pyorrhea in the young—between 20 and 40—in which known factors are absent Nothing remains then but to accuse infection, but this theory is not upheld by the results of research The author had a singular case of a patient who had had his appendix and gallbladder removed and a gastroenterostomy without relief from intestinal symptoms The little tongues of gingival tissue between the

three or four The exposure is directed to the anterior chest wall, as there seems to be no advantage in dividing the dose anteriorly and posteriorly A small cone should be used to confine the rays to the hilar area and attention must be given to protection of the thyroid area, especially in older children No attempt is made to avoid the thymic area, the feeling being that if there is a coincident thymic enlargement it will be the better for receiving its share of radiation The use of Roentgen therapy as a prophylactic measure also seems to be of value, as it has been noted that the disease failed to develop when exposed children in the same family were treated as well as the patient The benefits to be derived from Roentgen therapy in pertussis are primarily a very prompt relief of the paroxysms of coughing with its attendant vomiting This usually occurs shortly after the first exposure In the majority of cases there is a distinct shortening of the usual long-drawn out course of the disease, and the associated complications are, as a rule, absent, owing to the relief of the cough All pertussis patients should be given the advantage of Roentgen therapy, as it can do no possible harm and usually will do great good—*Southern Medical Journal,* June, 1929, xxii, 6

Nature of Grippe—Prof Paul Krause writes briefly on a recent epidemic of grippe in which 111 patients were treated There could be no doubt of the transmission from person to person which was seen over and over by physicians and nurses who were moreover themselves infected in a large share of the exposures The course was mostly mild and Pfeiffer's bacillus was found in but 87 per cent of the cases—this despite the fact that a new technique is now employed which is said to be superior to the old When pneumonia developed the germ usually found was the pneumococcus Type II But despite the paucity of the positive Pfeiffer cases the author believes firmly that that organism is the cause of grippe There was rather a poverty of symptoms in this epidemic—merely headache, backache, and catarrh of the upper respiratory tract There was but one fatality, in a man of 39 who had developed pneumonia There was difficult diagnosis in certain masked cases, one passing for typhoid fever until the negative Widal test showed the contrary In another case appendicitis was the first diagnosis Angina was present in 23 patients, mostly in people who were subject to sore throat. About half of these anginas presented the peculiar condition regarded by some as pathognomonic of influenza—a narrow strip of red on the free border of the soft palate The total number of pneumonia cases was 10 The patients were put to bed and the milder cases required only hydrotherapy for the headache The only drugs used were sodium salicylate and acetylsalicylic acid In pneumonia with pneumococcus present antipneumococcus serum was used, polyvalent while waiting for typing and afterwards the specific serum The improvement under serum treatment is often striking and the author warmly recommends it. He would always use oxygen inhalations and some form of hydrotherapy A few drops of iodine tincture in a glass of water make the best gargle for the angina and he also advises adrenalin inhalation—*Deutsche medizinische Wochenschrift,* June 7, 1929

The Heart in Pregnancy—T P Sparks, Jr, urges the necessity of the diagnosis of heart disease early in pregnancy, in order that treatment may be promptly instituted when signs of a break in compensation are imminent. Failures occurring early in pregnancy should always give rise to a guarded prognosis, since the heart is failing at a time when it has not reached the period of greatest strain Myocardial failure is one of the most serious lesions complicating pregnancy Endocarditis is just as serious, and the probability of carrying through labor with one of these complications is always extremely doubtful. With these conditions the sooner pregnancy is terminated the better the prognosis Mitral stenosis is regarded as the next most serious lesion, particularly if it is due to rheumatic fever Mitral insufficiency and aortic insufficiency seem to exert a less damaging effect on the course of pregnancy and are not regarded as seriously as the above-mentioned lesions The management of patients having heart defects other than myocardial failure and endocarditis becomes a matter of attempting by every possible means to maintain the cardiac reserve If failure does occur and the heart muscle shows an inability to come back after a reasonable period of time under treatment, interruption is also indicated here, but statistics show that in most of these cases interruption will rarely be necessary The anesthetic is important in these cases Nitrous oxide and oxygen anesthesia is preferable if an operative procedure is indicated, if it is not available, ether may be employed provided the surroundings do not contraindicate its use—*Southern Medical Journal,* June, 1929, xxii, 6

Wound Healing and the Acid-Base Equilibrium—Dr H Kalk of the Second Medical Clinic at Charité Hospital, Berlin, refers to

LEGAL

INSANITY—EFFECT ON THE MARITAL CONTRACT

Important changes have been wrought by the Legislature of this State in the last year or so in relation to the annulment of a marriage on the ground of insanity We will discuss these legislative changes in two editorials, in the first of which we shall deal with the right of a sane spouse to annul the marriage on the ground of insanity unknown at the time of entering into the marital contract In our second editorial we shall consider a recent statute which gives either spouse a right to annul the marriage on the ground of incurable insanity subsequent to the marriage and existing for at least five years

About two years ago, there was presented to our Court of Appeals for decision an action brought by a husband against his wife to annul their marriage The case came before the Court on the following facts

The plaintiff was married to the defendant in the year 1912 In his complaint he claimed that unknown to him, she was then a lunatic wholly unable to understand the nature of the contract of marriage and its effects and consequences Two children were born of the union After the parties had been married for a period of ten years, the lunacy of the wife was established by appropriate judicial proceedings The complaint was dismissed in the Court below for failure to state a cause of action The question presented to the Court of Appeals was whether a marriage, voidable for insanity, may be annulled at the suit of the spouse who is sane

Under the statutes of this State as they stood at the time that this question was presented to the Court for consideration, a marriage might be annulled on the ground of idiocy or lunacy existing at the time of the marriage, by any relative of the idiot or lunatic, or if no suit for such relief was prosecuted by such relative, then on the application of any person admitted by the Court to prosecute as the next friend of such idiot or lunatic The marriage of a lunatic might also be annulled on the application of the lunatic after the restoration of reason, if the parties had not freely cohabited as husband and wife after the lunatic was restored to reason

On principle, it would seem that a reciprocal right, with appropriate restrictions, should be granted to the sane spouse, but the Court was of course limited in its decision to the language of the statutes controlling the facts before it In the consideration of the question, the Court assumed, as it was bound to, the truth of the allegations in the plaintiff's complaint, namely, that the wife was a lunatic at the time of the marriage and that the plaintiff husband was ignorant of her condition

In a very able opinion, Chief Judge Cardozo, writing for the Court of Appeals, held that under the statutes as they then existed, the husband was without relief to avoid the marriage In discussing the problems of public policy involved in the question before the Court for consideration, Judge Cardozo said

"There remain some considerations of public policy that are not to be ignored If a sane husband may avoid a marriage for the insanity of his wife, the question will come up whether he may put his wife aside though her insanity was known to him when the marriage was contracted * * * One may doubt whether the Legislature of New York, if it had supposed that such a right of action had been created or preserved, would have been less diligent to safeguard the remedy with appropriate restrictions The trouble does not end, however, with the moment of the marriage Problems difficult of solution will arise where the husband, though ignorant at the beginning, cohabits with the wife after her insanity is known There is instinctive revolt against the notion that infirmity of the mind shall be used as a pretense for relief against satiety of the body In this very case, plaintiff and defendant lived together for ten years The insanity is alleged to have existed from the beginning, yet as late as six years after the marriage a child was born of the union One would suppose that the cases must be rare indeed in which insanity so acute as to vitiate a marriage * * * could remain so long concealed Indeed, the plaintiff does not tell us when it was that the defendant's affliction was discovered His allegation is merely this, that the affliction was not known at the moment of the marriage If a marriage so contracted is voidable in its inception at the instance of the husband, shall later cohabitation with his wife after her insanity is known be taken as ratification or affirmance or inequitable conduct that will defeat the right of action? * * * The Legislature was careful to provide that annulment should be refused at the suit of the insane spouse if cohabitation continued after sanity was restored It has said nothing as to the rights of the other spouse where there has been continued cohabitation after the insanity is discovered In a code so precise and comprehensive would it have been satisfied to leave so much uncovered had it supposed that its enumeration would not be taken as exclusive? If so, the reciprocal right of action is first to be

teeth were swollen and congested A drop obtained antiseptically from one of these was cultured on gelose, and a streptococcus culture so obtained was used as an autovaccine with brilliant results amounting to complete recovery Since that time the author has frequently encountered the coincidence of these gingival lesions with infections remotely situated—felons, boils, intestinal lesions, etc The microbes concerned may be the *Staphylococcus albus* and *aureus,* the *Streptococcus parvulus,* and others He now has a material of this sort comprising a dozen cases But why is this portion of the gum attacked in these cases? The author in reply quotes the view of Retterer, expressed in 1922, that the gum is a lymphoid organ like the tonsil and appendix, Peyer's patches, etc When any of these structures are involved the tissue of the gum may also be involved in the selective action of the microorganism, and the latter and its toxins lower the resistance of the tissues, the resulting infection extending to the development of a lysis of the jaws comparable to that from chronic osteomyelitis To cure pyorrhea, then, it may be necessary to eliminate a focus of infection at a distance—*Bulletin de l'Académie de Médecine,* May 21, 1929

Conception and Limitation of Eczema.—Dr Carle, a dermatologist of Lyons, states that during the XIX century the word eczema was used to comprise all dermatoses which presented a common appearance Many of these were regarded as of internal origin But after 30 years of work in microscopic study, in culturing microorganisms, in following up the evolution of the lesions, and finally in the results of treatment, we have reached the conclusion that the determining cause is often enough of external origin The causal factor may be a fungus or a bacterium which is able to give rise to the most dissimilar lesions These organisms penetrate into the follicles, accumulate in the folds, infect small traumata, etc, and often the resulting disease may be connected with the occupation These lesions are best thought of as examples of dermatitis—the author prefers the term epidermitis for the superficial forms—which require only local treatment The term eczema should be reserved for that large group the causes and nature of which are still unknown In the present paper the author does not discuss this residual group at all, but devotes all his effort to a classification of the epidermitides He isolates a group due to fungi and fungoid organisms—dermatomycoses of some authors Here belong such diverse affections as eczema marginatum, dysidrosis, the various tineas, etc A second group is due to bacteria—chiefly the staphylococci and streptococci—and when the organisms in question penetrate into the follicles deep-seated and obstinate lesions result—furuncles, nonparasitic sycosis, etc A third group attributed to coccidia comprises seborrheic eczema, pityriasis, etc Finally one may make a special group of professional dermatoses, for in these we find a traumatic factor with subsequent infection by fungi or bacteria. Superficial forms are readily amenable to local measures, but in deep-seated follicular lesions physical therapy, vaccines, etc may be required—*Le Journal de Médecine de Lyon,* May 5, 1929

Cigarette Smoking—A. Winterstein and E Aronson have made researches on this habit in the Technical High School of Zürich Nicotine is, they hold, the leading toxic ingredient of cigarette tobacco and 4 milligrams will cause symptoms which may persist for 24 hours Five "mild" cigarettes actually contain a fatal dose of nicotine. Cloetta has shown that nicotine can give rise to symptoms ordinarily unrecognized as such There is no legislation which tends to cut down the consumption of cigarettes and the tendency of their consumption to increase is being noted all over the world There is no actual distinction between mild and strong cigarettes in regard to percentage of nicotine and these terms as used in the cigarette industry mean but little. It would certainly be impracticable to legislate against the use of tobacco as a whole, but it should be practicable to insure a "hygienic" cigarette although thus far attempts in this direction have not been very successful It is now possible to limit the nicotine percentage to a given figure and it is possible to show by tests on living tissue—the leech for example—that the percentage is in accordance with that designed Analyses on brands of cigarettes bought in the open market show that the nicotine content may vary from 0 7 per cent to 3 per cent We also know how much smoke reaches the buccal cavity in smoking—somewhere between one-fifth and two-fifths of the smoke formed It is estimated that the inhaler absorbs about three times as much nicotine as the non-inhaler Long and thin cigarettes contain less nicotine than short, thick ones while dry ones contain more than moist ones It might be possible to pass laws against the sale of cigarettes containing more than 0 4 per cent of nicotine and even if the smoke of these were inhaled the amount of the alkaloid absorbed would not be dangerous The authors do not seem to favor extraction of nicotine but rather of growing strains of tobacco with low nicotine content.—*Schweizerische medizinische Wochenschrift,* May 25, 1929

NEWS NOTES

SECOND ANNUAL GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The New York Academy of Medicine has completed its program for the Second Annual Graduate Fortnight The First Fortnight was held during the first two weeks of October 1928, and was described in this Journal in the issues of September 15 and October 15 The announcement of the second Fortnight was made in this Journal on February 15, 1929

The Committee in charge of this year's Fortnight consists of Dr Harlow Brooks, Chairman, and Drs Louis Casamajor, Ludwig Kast, Emanuel Libman, Howard F Shattuck, and Allen O Whipple This Committee has chosen for the subject of the Fortnight "Functional and Nervous Problems in Medicine and Surgery" The field includes those functional disturbances which have been much neglected in the last thirty years in comparison with the structural disturbances of the human body The topic covers differential diagnosis of functional and organic derangements in all branches of medicine and surgery

The plan of the 1928 Fortnight will be followed this year Clinical programs will be conducted in the larger hospitals in the afternoon, and formal lectures will be given in the evening in the Academy building at 2 East 103rd Street

The scope of the evening lectures is indicated by the following program of the first three days

The Medical Profession and the Public Good, Dr Livingston Farrand, President, Cornell University

The Graduate Fortnight and Graduate Medical Education, Dr Ludwig Kast, Professor of Medicine, New York Post-Graduate Medical School

Origin and Growth of the Mental Hygiene Movement, Mr Clifford W Beers, Founder, National Committee for Mental Hygiene

The Involuntary Nervous System, Dr Walter Langdon Brown, St Bartholomew's Hospital, London

Hysteria as a Practical Problem, Dr C Macfie Campbell, Professor of Psychiatry, Harvard University

Neuroses Following Accident, Dr Foster Kennedy, Cornell University

Sympathic Ganglionectomy, Dr Alfred W Adson, Mayo Clinic

The character of the afternoon clinics may be judged from the following numbers which are the two appearing first on the program

Babies' Hospital, October 8

The neuropathic child, Dr Nathaniel R Norton.

Cretinism, Dr Herbert B Wilcox

Psychic disturbances as seen in private practice, Dr F Elmer Johnson

Bellevue Hospital, October 8

Vegetative nervous symptoms in the course of encephalitis, Dr Foster Kennedy

Surgery of the sympathetic, Dr Alfred S Taylor

Trophoneuroses and the central sympathetic, Dr Walter K Kraus

Vegetative nervous system phenomena in the psychoneuroses, Dr Thomas K Davis

A twenty four page program has been prepared and will be sent to those who inquire for it The members of the Medical Society of the State of New York are cordially invited to attend the Fortnight and to make use of the hospitality of the New York Academy of Medicine

---

THE NEW DIRECTORY

Copy for the Annual Medical Directory of New York, New Jersey and Connecticut was sent to the printer in August, and the reading of the proof should be completed by the end of September

Each year there are a number of physicians who delay sending their new addresses, telephone numbers, etc, until all the proofs have been read and the pages made up It is therefore very important if there are any changes in your record for the Medical Directory that you send them at once to the Medical Society of the State of New York, 2 East 103rd Street, New York

inferred by recourse to a process of construction, and then by a new process of construction is to be burdened with implied conditions Uncertainties are not exhausted with the cases thus supposed A spouse insane at the time of marriage may subsequently be restored to reason If the wife, becoming sane, confirms the marriage, as she may, will judgment go for the husband to the effect that it is void? These and like queries suggest embarrassments and complications that may have seemed to the Legislature to find their readiest solution in the denial of a remedy as easily abused"

It was strenuously argued by counsel for the husband that if the Court failed to give the husband the relief sought, it would work a great injustice and hardship to him Answering these contentions, Judge Cardozo further said

"Much is said about hardship Not all of it is of such a nature as to be heeded by the law The theory of annulment on the ground of insanity is not that the sane spouse has made a bad bargain in getting an insane partner The theory is that the insane partner to the union has manifested a consent that is unreal for lack of a contracting mind The hardship might be as great in many of its phases if insanity supervened a month after the marriage or a year It might be as great if the diseased condition were one of body and not of mind The law turns a deaf ear to these and like regrets

When all deductions are allowed, there remains none the less, in possible situations a residuum of hardship that may be thought to be special and peculiar One of the parties to the marriage, though innocent of wrongdoing, is condemned to uncertainty as to his or her status unless the other party to the marriage or an appointed champion is willing to dispel the doubt The statute relieves such uncertainty from the worst of its incidents by fixing the status of the children irrespective of any suit. They remain in any event the legitimate offspring of the sane parent This has been so since the days of the Revised Statutes * * * They may now be declared legitimate as to the other parent also * * * Uncertainty remains to some extent in respect of rights of property incidental to a marriage It remains, aside from legal consequences, a foe to peace of mind, a disquieting reminder of anomalous position. Considerations such as these may suggest an amendment of the statute that will extend the right of action Good faith can be assured by coupling the extension with appropriate conditions"

Judge Cardozo's suggestion that a consideration of the questions which formed the subject-matter of his opinion might lead to an amendment of the statute, bore fruit in 1928 when the Legislature amended the Civil Practice Act so far as to give the sane spouse a reciprocal right to annul the marriage The amendment reads as follows

"Where one of the parties to a marriage was a lunatic at the time of the marriage, an action may also be maintained by the other party at any time during the continuance of the lunacy, provided the plaintiff did not know of the lunacy at the time of the marriage"

It is to be regretted that the Legislature did not fully meet the points raised by Judge Cardozo's decision Although, as the learned Court pointed out in its opinion, cohabitation by the sane spouse after discovery of the insanity would in all probability operate as an estoppel in an action by the husband to annul the marriage, nevertheless it would have been a simple matter for the Legislature to include in the statutory amendment above referred to a clause that no annulment should be granted in the suit of the sane spouse where there was cohabitation after the discovery of the insanity

PURPOSE IN LIFE

Social workers may be so much concerned with far-off results that they overlook immediate needs It may be that the doctor is likely to put too much emphasis on the immediate need of the patient,—to secure for him the absolution for his past offenses, and then to turn him loose to repeat his misdeeds

Doctors will appreciate the following item by Edward Hope in his column called "The Lantern" in the New York *Herald-Tribune* of August first

"College students, a minister said in his sermon the other day, have no purpose in life. But has the Rev gent ever seen one just as he catches sight of a pretty girl or a gin bottle? And what is a Purpose in Life, anyway? Our own idea is that it is something you think up to write on a questionnaire, or something that occurs to you suddenly when you are making character with a member of the Other Sex"

FREE SERVICES BY BARBERS IN HOSPITALS

Barbers were the original surgeons, and following the example of their illustrious successors they are claiming credit for free services given to patients in the hospitals of Brooklyn The *New York Times* of August 14 has the following to say regarding free services of barbers —

"More than $3,000 worth of free services are rendered by barbers in Brooklyn hospitals, according to hospital superintendents Patients who are unable to pay are taken care of without any charge by those barbers who work in the Brooklyn institutions, the superintendents said

"At the Jewish Hospital a regular barber shop with two barbers and a manicurist are maintained All the children in the wards are taken care of without any charge, the superintendent there said Such patients as are convalescing and who are able to walk to the shop also are taken care of there. While on his rounds, the barber tidies the hair of or shaves those persons too ill to get out of bed The superintendent of the Jewish Hospital said that these barbers give about $1,000 free service yearly"

If the free hospital services given by barbers are worth three thousand dollars annually, then those rendered by physicians are worth thirty million

---

HUMAN BAROMETERS

Doctors scoff at a lot of popular notions until they themselves acquire them Rheumatism is a reliable barometer to many persons and this fact, if not the reason for it, is confirmed by scientific research This idea is expressed in the following verses by James J Montague in the department "More truth than poetry," in the *New York Herald Tribune* of August 14 —

'When Uncle Abner used to say
'We're goin' ter have a rain.
When I was pitchin' hay today
My knees begun to pain
I quickly turned away, because
Though I was young in years,
I felt convinced by uncle was
Too soft between the ears

When Aunt Eliza would remark
In shrill, prophetic tones
The snow'll be three foot deep by dark
I feel it in my bones'
My head I smilingly inclined
But did not deign to speak,
I thought that the old lady's mind
Was getting rather weak

'But now a scientist maintains—
And proves it, if you please—
That changing weather *does* cause pains
In people's arms and knees
And when they say 'It's goin' to snow
Or mebbe sleet tonight,
My legs is achin', so I know'
They usually are right

Today I frequently deplore
My children's want of tact
They've got to doubting, more and more,
That I state only fact
But well those scientific chaps
Their work have gone about,
And in a few more years, perhaps,
My kids will just find out!'

THE DAILY PRESS

THE HAY FEVER SEASON

The hay fever season is now approaching its height, and the affection is becoming copy for newspapers It is real news that the city of New York finds it necessary to compel landowners to cut the noxious weeds beside the streets, as though the city were a country hamlet An opposite phase of the problem—the susceptibility of individuals—is discussed editorially in the New York *Herald-Tribune* of July 20 as follows

"Hay fever sufferers have a right to demand, of course, that medical science discover the fundamental cause of their disability, for this cause certainly is not the mere pollen in the air, but is the mysterious something in blood or body which makes certain individuals susceptible to the pollen proteins while other individuals are not In spite of much active and intelligent work on this and other diseases of the same class, the so-called allergies, the secret proves illusive Banishment of the hay fever plants from the city is admittedly a temporary expedient, pending further medical knowledge, but an expedient which New York's vast army of sufferers is likely to find exceedingly grateful"

SERVICE WORTH WHILE

The medical profession with its array of experts and specialists is like a big department store in which the customer takes what he wants, and the salesmen stimulate him to buy regardless of his needs and his finances

Both physicians and the managers of department stores are beginning to realize that they are educators as well as money getters A large advertisement of a big department store in the New York *Times* of August 5 emphasizes the service which the store renders in the making of household budgets That particular advertisement is directed to the customer who has a $100,000 income, and is as likely to be in debt as the thousand-dollar laborer

The spendthrifts of health are found among the rich, the refined, and the educated quite as often as among the poor, and physicians are as eager as floorwalkers to gratify their fancies The closing words of the advertisement apply equally well to both department stores and the medical profession

"This personal interest is highly appreciated It is a delight to hear the customers' comments They think it is wonderful not to be urged to buy either extravagantly or extensively They like the co-operation they get in their buying They feel they are being guided to buy wisely This cements the close ties between the store and its customers It is a marvelous demonstration of faith and good will"

GLAMOUR IN ADVERTISING

The first essential in an advertisement is that it shall not merely invite a casual reading, but it shall compel the attention of one who idly turns the pages The user of the advertised article is sure to experience something of the bewitching enchantment which he felt on the discovery of the alluring advertisement.

The *New York Times* of August 9th discusses advertising glamour as follows

"'Glamour' without lies or insincerity is the watchword in the new school of advertising

"Suppose when I spend a quarter for tooth paste I do pay two cents for literal cleanliness and twenty-three cents for glamour—what, after all, more precious would my money buy?

"So long as advertising writers confine their glamourous words to harmless gush there can be no protest on moral grounds But competition is keen, and exaggeration grows by what it feeds on Many advertising agencies maintain a strict self-censorship, however, and little downright untruthfulness gets past it Even when they tell us that 'nothing gives such an air of elegant sophistication' as a certain type of cloth for suits, or that 'this face lotion is compounded according to a formula favored by the aristocracy of Europe for fifty years,' most of us smile a little incredulously Then we go out and buy the suit and the lotion"

editions The methods described are those that have definite clinical application

The book is especially recommended to the medical student and the medical man of limited laboratory experience.

H M Feinblatt

Handbook of Bacteriology for Students and Practitioners of Medicine. By Joseph W Bigger, M.D Second Edition. 12mo of 452 pages, illustrated New York, William Wood & Company, 1929 Cloth, $5 00

This is the second edition of a text-book written primarily, as the author states, for medical students, rather than for those specializing in bacteriology The author has condensed in a small volume all the facts pertaining to bacteria as the causative agents of disease in man with a minimum amount of theoretical and laboratory procedure.

I. Cohen

Angina Pectoris By Harlow Brooks, M D 16mo of 164 pages New York and London, Harper & Brothers, 1929 Flexible leather, $2 50 (Harper's Medical Monographs)

This is the second volume of Harper's Medical Monographs which are attractive books of convenient size which should prove very helpful to the practitioner The author after a review of historical facts, discusses what is known of the etiology, pathology and symptoms, with special attention to treatment, of angina pectoris

With regard to the pathology, he believes that disease resulting in stricture of the coronary lumen is the most common finding but is not the entire basis for the disease. Ischaemia of the heart muscle, myocardial disease and aortitis are discussed If syphilis is found to be present, before arsphenamin is used, the patient is brought under the influence of iodides and mercury or bismuth Angina pectoris caused by gout is said to occur and to yield to treatment with colchicine and cinchophen Toxic angina caused by tea, coffee and especially by tobacco receives consideration, the latter is stated to be the most common cause of the condition

For the attack the usual remedies are advised. Drugs of the caffeine type theobromine theophyllin and euphyllin (now called metaphyllin), which are said to dilate the coronary arteries, are used by the writer, but he is skeptical as to their beneficial effects both for the attack and as a measure of prevention

W E McCollom

Thyroxine. By Edward C Kendall M S, Ph D, D Sc Octavo of 265 pages, illustrated New York, The Chemical Catalog Company, Inc., 1929 Cloth, $5.50 (American Chemical Society Monograph Series)

"Thyroxine" is volume number 47 of the American Chemical Society Monograph Series It embodies the results of more than fifteen years study of this subject on the part of the author as well as a critical presentation of the findings and theories of other investigators, the bibliography contains 541 references

The earlier physiological and chemical studies of the thyroid gland are discussed. The history of the preparation of the various active extracts from the gland is traced up to the isolation of crystalline thyroxine The chemical and physical properties of thyroxine are described, and account is given of the synthetic preparation of thyroxine.

The clinical aspects of thyroid dysfunction are presented and the underlying chemical etiology is discussed Among the topics treated may be mentioned hypo- and hyper-thyroidism, myxedema, basal metabolism, and biological oxidations Chapters are devoted to the influence of the thyroid on nitrogen, carbohydrate phosphorus and calcium metabolism. A chapter is given to the "Standardization of Thyroid Material"

The Board of Editors of the American Chemical Society Monographs and the author have rendered clinicians and investigators an invaluable service in presenting this authoritative monograph

M J Shear.

Manson's Tropical Diseases A Manual of the Diseases of Warm Climates Edited by Philip H. Manson-Bahr, D S O, M.A, M D Ninth Edition, revised Octavo of 921 pages, illustrated New York, William Wood & Company, 1929 Cloth, $11 00

The author is very modest in calling this volume only "an introduction to the important department of medicine of which it treats" The 889 pages of this book contain more information on the tropical diseases than one would expect to find in two such volumes Although meant especially for those living or traveling in the tropics, the contents of this book so clearly emphasizes the importance of this department of medicine that every physician should be encouraged to own this volume at least for reference. The material is presented in the light of recent investigations The plates are fascinating and in themselves educational The clinical methods employed are the best and are fully described so that they can be carried out accurately by the reader Lastly, the emphasis on treatment is an important feature of this new edition The book is highly recommended

S H Polayes

The Diagnosis and Treatment of Tropical Diseases A Compendium of Tropical and Other Exotic Diseases By E R Stitt, A.B, Ph.G, M D Fifth Edition, revised Octavo of 918 pages, illustrated. Philadelphia, P Blakiston's Son & Company, 1929 Cloth, $9 00

The present volume of about 900 pages is exceptionally well illustrated and presents a large and interesting amount of material not covered in former editions

Among the new subjects of interest described are Melioidosis (glanders-like disease of Rangoon), food injuries and vitamine deficiencies, injurious plants, common cosmopolitan helminthic infections, injurious arthropods, fish and coelenterates, and poisonous snakes.

Under malaria, a discussion of the value of plasmochin and of the use of malaria induction in the treatment of paresis are ably presented

A section on laboratory procedures which is concise and yet detailed and complete adds much to the value of the book

We can most highly recommend the volume to the general practitioner and the special worker as a reliable book of reference

H M Feinblatt

Ante-Natal Care. A Practical Handbook of Ante-Natal Care and of the Abnormalities Associated with Pregnancy By W F T Haultain O B E, M C, M B, and E Chalmers Fahmy M B, F R C S E. 12mo of 113 pages New York, William Wood & Company, 1929 Cloth, $2.25

This book is a practical handbook of Ante-Natal care, and of the abnormalities associated with pregnancy

In the first part of the book, the authors consider the diagnosis and hygiene of pregnancy, together with methods of pelvic mensuration and general examination of the pregnant patient

In the latter part of the volume, the various abnormalities which occur in pregnancy are set forth in considerable detail

The book is small, yet the authors have succeeded in crowding a great deal of valuable material into a very small space. It teaches well the importance of Ante-Natal care during pregnancy

W S S

BOOK REVIEWS

A Shorter Anatomy With Practical Applications By E Wolff, M D, B S, F R C S Octavo of 451 pages illustrated New York, William Wood & Company, 1929 Cloth, $6 00

The text and drawings of this volume are based upon lectures and demonstrations given by the author to the students of University College and Hospital and the Slade School of Art

There are 440 pages of text which deal with the anatomy of the body in a short descriptive manner, illustrating the relationships by drawing The student is encouraged at all times to use his body in making anatomical observations

For the student of anatomy, this volume lacks much of the important detail, particularly as regards anatomical relationships

The skeletal muscular groups are stressed as regards their various movements and actions, also their surface form

There are about 130 illustrations, most of which are drawings by the author There are also about 15 *x*-ray pictures showing the bony anatomy, with four of the *x*-ray group illustrating the various positions of the gall-bladder

The brevity and arrangement of the text makes this a valuable ready reference book on this subject It should also be an extremely valuable asset to the student and teacher of artistic anatomy

H T Wikle.

Surface Anatomy By Arthur Robinson, M D, F R C S, and E B Jamieson, M D Octavo of 175 pages, illustrated New York, William Wood and Company, 1928 Cloth, $6 00 (Oxford Medical Publications)

With the already existing number of dissecting manuals another would amost seem superfluous, however, this short volume of 160 pages of text and 38 drawings with 24 in color, deals with surface anatomy and comes from a school whose anatomical accuracies are a by-word in the profession, which should make it command the attention of the student of anatomy

The text is concise, the drawings are well done and accurate. The subject matter is taken in orthodox sequence starting with the head and including a chapter on the back.

The old imaginary line marking on the surface is little used, the structures are located by definite anatomical points and structural relationships

Although this is a volume essentially for the student of anatomy, it should be of great benefit in the teaching and study of physical diagnosis, its conciseness increases its value in this field of study H T Wikle.

An Index of Symptomatology By various writers Edited by H Letheby Tidy, M A., M D Large octavo of 710 pages New York, William Wood & Company, 1929 Cloth, $12 00

This volume of seven hundred and ten large pages and one hundred and thirty illustrations contains a wealth of information arranged in alphabetical order and gives a clear description of the symptoms of each disease It covers all the branches of medicine and surgery and the special subjects, the work of the numerous contributors in the different fields making this broad scope satisfactory They are all well known English clinicians and have produced a first class work, which makes a companion volume for French's Index of Differential Diagnosis by the same publishers

It is a convenient and valuable reference book

W E McCollom

Getting Ready to Be a Mother. A Little Book of Information and Advice for the Young Woman Who Is Looking Forward to Motherhood. By Carolyn Conant Van Blarcom, R N Second Edition, revised 12mo of 286 pages, illustrated. New York, The Macmillan Company, 1929 Cloth, $1 75

When a book reaches the second edition, it passes from the experimental stage and becomes one of the volumes that have been proved, and found to be of value. In this second edition, the author has revised some of the contents of the previous edition, and has added some of the latest bits of information for the expectant mother

The volume is divided into two parts Part one deals with the mother and her unborn babe, and covers the prenatal period. Part two deals with the baby after it has arrived

The book is very readable. The language is simple, and the advice given to the expectant mother is sound, practical, and of great value

It is to be hoped, that as time goes on, all mothers will be instructed in just such simple, but necessary truths, as are to be found in this little volume

We wish for it all the success of the former edition.

Wm Sidney Smith

Surgery in the Tropics By Sir Frank Powell Connor, D S O, F R C S Octavo of 293 pages, illustrated. *Philadelphia*, P Blakiston's Son & Company, 1929 Cloth, $3 50

The author claims that this little book is meant to supplement the teachings of standard textbooks of surgery only In the opinion of the reviewer it actually accomplishes very much more Not only is the "tropical point of view" adequately and attractively presented, but the essence of good judgment in surgery in general is brought home to the reader in a remarkably clear-cut and eminently practical style. The illustrations are numerous and are well selected To the surgeon beginning to work in the tropics this book will be a source of great comfort and inspiration.

Geo Webb.

Recent Advances in Obstetrics and Gynaecology By Aleck W Bourne, B.A., M B, B Ch. Second Edition 12mo of 382 pages, illustrated Philadelphia, P Blakiston's Son & Company, 1928 Cloth, $3.50

Recent progress in obstetrics and gynecology is set forth in a very engaging manner Though much of the material is not new, the subjects selected for discussion are very clearly presented. Excellent drawings illustrating the mechanism of septal tears in intracranial hemorrhages are included. The management of placenta praevia is surprisingly different from our own, and a strong case is made out for "vaginal plugging" without bags or version Prolapse is well done, and the end results of surgery in Cancer of the Cervix are compared with the results of radium For anyone interested in gynecology or obstetrics the book is well worth while

C A G

Practical Clinical Laboratory Diagnosis A Thoroughly Illustrated Laboratory Guide Including the Interpretation of Laboratory Findings Designed for the Use of Students and Practitioners of Medicine By Charles C Bass, M D, and Foster M Johns, M D Third Edition, revised Octavo of 187 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1929 Cloth, $7.50

This small volume of about 180 pages is well illustrated and is written in much the same style as the former

It doubles misfortune to have to pay twice!

For instance, vacation expenses and post-vacational illness

The return from vacation is being followed, this year, by intestinal disturbance, frequently diagnosed is "intestinal Grippe" It develops in babies, in children and in many adults

Treatment is symptomatic and Dietetic

Dietetic Means DRYCO

DRYCO is free from pathogens, easily digested, almost completely assimilated, simple to prepare and utilized when other forms of of milk are ineffective or not tolerated

Proscribe other feeding agents. Prescribe DRYCO

NOTE THE PROMPT RETURN TO NORMAL

Send for DRYCO samples, suggested feeding tables and clinical data Just pin this to your letterhead or Rx blank and mail

OUR NEIGHBORS

MEDICAL DEFENSE IN OKLAHOMA

Some members of the Oklahoma State Medical Association seem to use their medical society for what they can get out of it, if one may judge by the following editorial from the July issue of that State Journal

"For the information of our members it is decided to call their attention to the terms upon which Medical Defense is extended and available At the outset it should be stated that formerly the Association undertook to pay all legal expenses Gradually it was noted that some of our members attempted to include every other conceivable form of expense The average amount spent in defending these cases was about $400 00 In one case more than that amount was expended and the next year the successfully defended member lapsed his membership and has never renewed One of the earliest cases ever defended cost the Association an expense bill of more than $400 00, he too, lapsed his membership and remained so This was so disheartening that it was decided to limit the maximum amount of expense in any one case to not more than $100 00

"One of the most irritating phases of it was the palpable lack of good faith shown in some cases In one case a member paid his dues, say on the 5th of May, was sued on the same date and expected the Association to defend his case, though his membership fee was not received until well along in June This member gravely stated that the first intimation that he was to be sued was received the day after he paid his dues Under the present rule—and they are positively binding—the following are necessities

"1 The member sued must have been in good standing upon the date of the alleged malpractice and *must have remained so continuously* (the only exception to this is that there is a month of grace, January of each year, in which the dues must be received in the office of the State Secretary)

"An example of how a member may get in trouble under the above rule is this He performs some service, say in 1928, he neglected to pay his dues, disregarding both notices from his County Secretary and the State Secretary, finally paying them in March or April, 1929 He is sued for alleged malpractice in May, 1929 He is not entitled to any aid, for his membership expired December 31, 1928 Had he paid his dues as late as January 31, 1929, he would have been entitled to defense

"2 Malpractice must be alleged. This money was not intended to be used in defending any other type of action Notwithstanding this it is not uncommon to receive requests for aid in other than malpractice suits

"3 Strictly speaking the Association should have prompt notice of a suit, a copy of the petition filed against the doctor and the names of his attorneys as well as those bringing the suit Of course if the suit is merely filed and never comes to an issue and the attorney's bill is a nominal fee of *$25 00* or *$50 00*, which is sometimes the case, the member is not entitled to the full amount of $100 00 to which he might otherwise be entitled In other words if his attorney fee is $100 00 or more and is expended in good faith in defending a malpractice suit, he is entitled to reimbursement to that amount"

INCREASING THE DUES IN THE ARKANSAS MEDICAL SOCIETY

The annual dues of the Arkansas Medical Society have been three dollars, but the House of Delegates on May 7 voted to raise them to five dollars The motion was introduced as the result of a proposal to employ an attorney The President of the Society, Dr R H T Mann, calling attention to the expense of the new office, said

"I think this is the place for this matter to come up Here is what I have to say about this The good of the Arkansas Medical Society, the health of the two million people living within this State, is too important not to be handled in the proper way and the five dollars, if it is to be raised to that, is an insignificant sum If we, through the Arkansas Medical Society, can give the physicians who are now practicing in this State and those who are to practice medicine in the future in this State, the best possible known conditions under which to practice, then I say that the five dollars is nothing compared to the benefits received by each physician who is practicing in the State Is there any further discussion on it? I want it to be voted on right here before the House"

(*Continued from page* 1092)

Dr Wm E Jones of Little Rock made a rather idealistic proposition as follows

"I am not a delegate, but I should like to say that I think, instead of raising the dues to five dollars, that we should make it ten, then, any amount of money that we do not need for the upkeep of our Society could be used in the students' loan fund to be paid back by those students when they get out in active work I think it is one of the greatest things we could possibly do for the upbuilding of our profession We have a number of young men in the State that would make wonderful physicians if they only had the opportunity to get started Our good friend from Fort Smith, who has the benefit of this loan, was the son of a very good friend of mine, who has been gone many years It doubtless has been a great boon to this young man to have had this loan, and it will be paid back and he will be very grateful for the use of it"

The Secretary, Dr W R Bathurst, feared that loss of members would follow the raising of the dues, although that result did not follow the doubling of the dues in New York State, Dr Bathurst said

"Having had some experience in collecting dues from over a thousand members for a good many years, I fear it will be difficult to raise the dues to five dollars This increase might appeal to you this morning while you feel the need of it, with a small number present, but our seven or eight hundred members not present may object seriously We shall lose at least 20 per cent of our members during the next year We will not be any better off financially, but I think in the following year we will get a large number back and eventually have our income increased It is a step we must take eventually and we might as well go through that depression at this time."

Dr Ware of Greenwood opposed both the employment of an attorney and the raising of the dues, and said

"I am not a delegate, but I would like to voice my sentiments against the employment of an attorney regularly If you are going in to spend money, of course, you will lose members I think that the dues can stand for at least a year, maybe two years, just what they are today It doesn't look well for organized medicine to jump in and let the public know we have employed an attorney regularly and we raised our dues It doesn't look well"

The Treasurer, Dr R J Calcote of Little Rock, showed the need of more money when he said

"In my report this morning, I reported some $2,950 00 less than I did last year So you see from that alone it might show we need an increase in dues Some of these days we shall

SAFE *and* SANE DIETING . . . *in* WEIGHT REDUCING! . . .

When weight reduction is advisable (*and a nerve-racking, unsatisfied appetite is inadvisable*)—then Knox Sparkling Gelatine may be used with gratifying results.

Knox Gelatine is beneficial protein—a wholesome delicacy that may be delightfully combined with vegetables, fruits, chicken and other foods in the weight reducing diet. There are Knox Gelatine salads, mousses and desserts which are well balanced dietetically but of low calorific value, *and will satisfy the most persistent craving for food.*

Knox Gelatine supplies the diet *bulk* that satisfies hunger—and the diet *variety* that appeases the appetite. Only Knox Gelatine should be used, because it is real gelatine in its purest form—unbleached, unflavored and unsweetened.

May we send you gelatine reducing recipes, specially prepared by recognized dietetic authorities? They will help you in your practice. Our other laboratory material is available also if you will return the coupon below. We should appreciate the opportunity of sending you the newest findings concerning the importance of gelatine in medical practice.

KNOX GELATINE LABORATORIES
432 Knox Avenue Johnstown N Y

Please send me without obligation or expense, the booklets which I have marked. Also register my name for future reports on clinical gelatine tests as they are issued.

need a full-time secretary Some of these days we would like to look forward to a permanent home, and we shall need money for these things when they come, and we might as well start now"

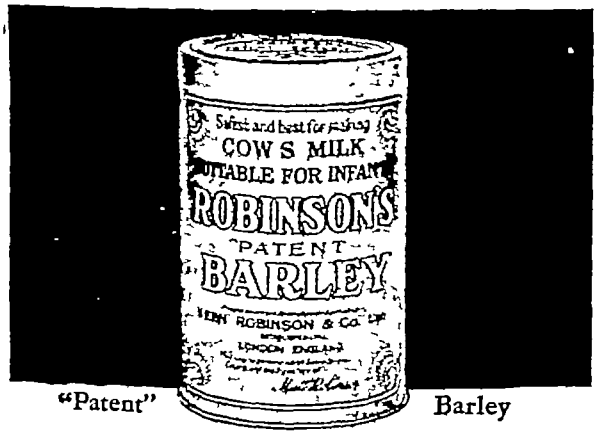
Dr Calcote's address apparently settled the question, for at the close of his address the House unanimously voted to raise the dues to five dollars

SCIENTIFIC WORK OF THE TEXAS MEDICAL ASSOCIATION

The leaders of the Medical Society of the State of New York are always interested in the activities of the State Medical Association of Texas as set forth by Dr Holman Taylor, Editor of the *Texas State Journal of Medicine* The July issue contains the following editorial comment on "The Scientific Work of the Texas State Association"

"Several years ago our House of Delegates inaugurated the so-called Council on Scientific Work This council comprises ex-officio, the President and Secretary of the State Association, the officers of scientific sections, and five members from the Association at large, carefully selected and elected on a five-year, overlapping term basis

"It is proposed that all of the scientific work of the Association shall be directed by this group Scientific sections will continue to function as s' ch, and their officers will have complete jurisdiction over the work of the sections, but the influence of the other members of the council will inevitably be felt by the officers of any given section, and the results must be more satisfactory than they would otherwise be No part of the function of any officer of any section is taken from him He is still responsible for the compilation of his program and for its execution, but he will both give and take advice Certainly in this manner the work of the sections will be coordinated



"It is within the province of this council to undertake any enterprise whatsoever of a scientific nature, either as a matter of research, coordination or education There are certain duties relegated to it by the written laws of the Association, and certain obligations imposed upon it by common consent It takes time for us all to appreciate the value of the plan Even the council itself is just beginning to reach its stride

"The President has selected for the major theme of the scientific work of his administration 'Early Diagnosis,' which subject involves, of course, the heretofore spasmodically conducted campaigns of 'Early Physical Examination,' 'Annual Physical Examination,' and the like He expects to bring to the aid of the Association many welfare organizations interested in such matters, when the time is ripe, but first he feels that the medical profession must get this particu-

Robinson's
"Patent" Barley *and* "Patent" Groats

Recommended by the medical profession for over a century

"Patent" Barley

Modifier of the curd of cow's milk thus increasing digestibility of protein and fat

Non-fermentable carbohydrate addition to infant milk mixtures

1—To assist gradual development of the infant's starch digesting functions

2—To replace more easily fermentable sugars

Thickening agent for preparation of thick feedings in vomiting cases

Bland soothing fluid for administration in the early stages of infantile fermentative diarrhoea

"Patent" Groats

Finely ground, standard preparation of Oats, with a definitely laxative action

Highly nutritious cereal for weaned infants

Nourishing addition to cow's milk in the diet of the expectant and nursing mother Suitably modifies the milk and imparts to it a pleasing flavor

Of especial benefit to invalids and convalescents where cow's milk so frequently forms the major part of the diet

Samples and descriptive literature on request.

grams and of encouraging members to make contributions to the literature of scientific medicine. Should an offer be rejected it would presumably mean that some other offer more nearly met the requirements of the section officers and the Council on Scientific Work It is not necessary that any one should be embarrassed Authors from whom contributions have been tentatively accepted, will then be expected to perfect their papers, and submit them to section officers If they meet with the approval of the section officers, they must then be read before county societies, or district societies, in accordance with the provisions of the by-laws"

ADMINISTRATION OF THE TEXAS STATE MEDICAL SOCIETY

The organization of the State Medical Association of Texas is similar to that of the New York State Society, as well as seen from the following editorial in the July issue of the *Texas Journal*

"The basic group of our organization, in addition to its executive and administrative officers as such, and its legislative body, is the Executive Council It is quite probable that those who devised the system hardly appreciated its value at the time A few years' experience with it has convinced all of those who have observed its operation, that it was about the wisest concept of our plan of control This group comprises the executive and administrative officers, the Board of Trustees, the Board of Councilors and the Legislative Committee Before the day of the Executive Council, when an executive officer desired advice, he called upon those whom he felt were competent to advise him Either that, or he took a snapshot at making a decision on his own account Today any question of sufficient importance to require a conference brings together those officers, councils and committees which have to do with the Association in its several activities, so that any decision arrived at may be said to be coordinated. A legislative problem, for instance, may require money If so, the Board of Trustees are a part of the council and can advise and, following the decision of the group, make the necessary appropriation If the legislative problem at the same time involves the work of the Board of Councilors, the councilors are there and can advise, and then be instructed If the president desires to inaugurate a publicity campaign, there are ready at hand in this group those who must put it into effect and those who must appropriate the money to cover the necessary expenses involved

"The Board of Trustees is now and has been for years, the custodian of the funds and finances

(*Continued on page* 1102—*adv xxii*)

HERMANN BOERHAAVE
(1668-1738)

His treatment of constipation included large and repeated bleedings, "diluting and antiphlogistic glysters" repeated several times a day, incessant hot drinks, and "fomentations of the like kind applied all over the belly and chiefly the application of live hot and sound animals, such as puppies or kittens."

EVIDENTLY the "Batavian Hippocrates" believed in heroic measures in treatment One of his critics, Baas, says that "his prescriptions were less effective than his personal appearance"

No such drastic measures are necessary today Agarol, the original mineral oil emulsion with phenolphthalein, simplifies and improves the modern treatment of constipation

Safe and convenient to use under all conditions, Agarol softens the intestinal contents and *gently stimulates* the peristaltic action, making evacuation easy and tending to reestablish normal function

of the Association, in fact, it constitutes the board of directors of the Association, so far as business matters are concerned The fact that the board is made up of a small group of members, elected on a five-year, overlapping term of office basis, enables it to adopt a permanent financial policy for the Association and with the expectation of carrying it out The by-laws very wisely provide, and it did so upon the advice of the Board of Trustees itself, that each year a tentative budget must be prepared by the Board and submitted to the House of Delegates for discussion and approval or disapproval No business organization will permit its business policies to be thrown into the discard by its stockholders, except through the regularly constituted board of directors, but there are some differences between our organization and that of one of an ordinary business character Therefore this provision that the membership of the Association may have, through its House of Delegates, an opportunity to play upon the responsiveness of its financial managers Through this system our organization has been able to carry on an ever increasing activity and at the same time lay up a surplus, which surplus bids fair in the course of a reasonable time, to assume such proportions as will relieve us from anxiety as to the future and at the same time produce sufficient income to lessen the contributions we must make by way of dues The trustees long ago very wisely decided that no matter what the efforts of the Association might be, or what campaigns it had on hand, some money should be saved each year At no time has an inordinate surplus been put away Through this system we avoid the financial extremes of organization work"

Concerning the councilors, the editorial makes the following comment which may be profitably considered by the New York Society

"It is our idea that the reason boards of councilors have lost their value is because they have not been given anything to do, that not a great deal has been required of them We have tried to keep our board busy, and it has generally functioned very well, indeed It is the duty of the individual councilor to organize the county societies in his district, approve their by-laws and get them into good working condition After that, it is his problem to keep them going, and at the maximum speed He is an officer of the State Medical Association, and not of the county medical society or the district medical society At the same time, he is of and from the profession in the district and may be depended upon to care for their interests, along with the interests of the State Medical Association as a whole In his efforts to keep county societies functioning at maximum efficiency, it will be necessary

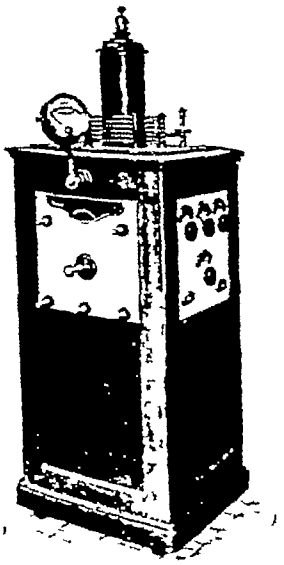
To Advertisers in the Medical Field

We officially and cordially invite you to join our large family of satisfied advertisers in the forthcoming annual edition of the Medical Directory of New York, New Jersey and Connecticut.

Its advertising sections share equally the importance of the Directory itself—a big factor in establishing co operative interest and good will between the organized medical profession and the carefully selected invited advertisers whose announcements appear on its pages The Directory is in daily use in more than 12,000 busy physicians' offices in New York, New Jersey and Connecticut.



When your advertisement appears in our Directory, you have definite assurance that your message will be read by just the physicians you want to reach, men who have come to regard the Medical Directory as a source of information next in importance only to the telephone book itself

Each advertiser receives copy of the Directory complimentary Regular price, $3.50

IMPORTANT

All advertisements published in the Directory must be ethical, and the formulas of medical preparations must have been approved by the Committee on Publication before they can be accepted.

for the Councilor frequently to settle disputes When he cannot do that with satisfaction to all concerned, it is the function of the Board of Councilors, as a whole, to make decision Such decisions are final"

Medical defense in Texas is of as much importance as it is in New York, as is shown in the following paragraph

"We would not overlook the importance of the Council on Medical Defense. One-tenth of our dues goes to support the work of this council That is a very small amount considering the importance of its work If it did not more than to keep our members and the insurance companies together and see that each does its part, it would be worth the price charged for it. It does much more than that Each year it takes exclusive charge of a number of malpractice suits brought against our members, without any cost whatsoever to the individual, and sees to it that there is no imposition practiced through that most potent and dangerous instrument of the blackmailer, the medical malpractice damage suit In addition to this service, the Council is virtually the legal advisor of the Association, and quite a respectable sum of money is spent in caring for the Association's litigation each year"

WHAT THE GEORGIA MEDICAL ASSOCIATION DOES

The annual address of Dr W R Dancy, President of the Twelfth District Association of Georgia touched on the work of the State Medical Association as follows, according to the July issue of the State Journal

"The Basic Science law you have heard much of It is very simple when analyzed It means that any one desiring to practice the healing art in Georgia should pass examinations on the Basic Sciences, which are anatomy, chemistry, physics, physiology and pathology Surely no right minded man, be he layman or professional man, can raise any objection to this It seems, however, there is some opposition

"The Health Program of the State Board of Health is heartily endorsed by the Medical Association of Georgia The necessity for larger funds to combat the present health situation in Georgia is imperative The physical business and economic welfare of our people and our state are dependent upon the control of disease Malarial fever and hook worm are again on the increase and recent storms, floods, and tornadoes have made harder the conditions of control The Sanitarium facilities for the care of mental defectives and tubercular cases are painfully inadequate, the preventable dis-

ease control situation is in dire need of greater physical and financial help, and I shall avail myself of this opportunity of urging all district societies to keep alive the effort of tick control in each of its counties

"Along the line of preventive medicine I would ask you to note that the chairman of the Cancer Commission whom your President recently appointed has caught step with the spirit of this administration and has begun his cancer campaign by personally presenting a paper on cancer I think it advisable and good policy for the commission to advise the citizens of the prevalence of cancer, its increase and its prevention in so far as we can

"A few years ago the American Medical Association adopted a recommendation of its committee that its component organizations organize for Medical Relief in Disaster The plan of organization was for the President of the Association of each state to be at the head of the State organization In counties the President of the County Society would head the organization If several Societies are combined into one Society the President of the combined Society would be the director in these counties The state director would be the President of the Medical Association of the State and the national director would be the manager or secretary of the American Medical Association acting under the advice of the President The work that this organization would do would be immediate relief in diaster Just as soon as possible after a great calamity has befallen a community the organized band of physicians of your county, at the request of your President Manager, would go without delay to the scene of trouble and function until the Red Cross, the United States Government or some organized bodies for this purpose arrive to take charge

"If we should sacrifice Medical Defense we felt that the physicians, particularly throughout the country districts, would not protect themselves with other insurance which would undoubtedly in some instances bring about unfortunate suits which in turn would reflect on the profession of this state Therefore, it was agreed to retain Medical Defense It was then necessary that the dues should be increased After a generous exchange of ideas the House of Delegates referred this matter to Council which decided that $7 00 per year should be the minimum dues The House of Delegates approved this and the convention of the Association adopted it This increase is a very small matter indeed, being about one-half a cent a

(*Continued on page 1108—adv xxvii*)

(*Continued from page* 1108—*adv xxviii*)

"We mention this subject because within recent weeks one or two publications have criticized the Association for going to the expense of maintaining a Bureau of Publicity which they consider of questionable value To our notion one of the most valuable features of the constructive work done by our Association is the creation and maintenance of the Bureau of Publicity with its splendid educational work Furthermore, it should be remembered that the expense is nominal, and the prominent medical men of Indiana who compose the Bureau of Publicity and who devote hours and hours of their valuable time to the work, are receiving no monetary compensation of any kind whatsoever and certainly no publicity

"It is unfortunate that some of the members of the Indiana State Medical Association do not know and do not try to find out how much time and trouble are devoted to constructive work for the benefit of the medical profession as well as the public by those who comprise the officers and committeemen of the Indiana State Medical Association. These men, to the number of two score or more, are working for the common good, with little or no thought of reward of any kind, but from a sense of duty as well as love of the work They deserve higher praise and we think they receive it except from the unthinking

STATISTICS IN MEDICAL PAPERS

The *West Virginia Medical Journal* always has a 'Presidents' Page," conducted this year by Dr H M Hall of Wheeling That page in the August issue discusses statistics in a medical paper as follows

'Any one who is arranging a program and includes a 'research worker' on the list knows what to expect—the audience will not be there as to numbers This is somewhat due to the manner in which these earnest, sincere men make up their papers They are too 'dry' and uninteresting Dr A. C Ivy, of Chicago, was always an exception The day will come when charts with maximum and minimum curves of incidence, long food tables with calories and percentages, statistical figures with matters involved and intensely mathematical, will not be given by a speaker, either by slides or otherwise, to an audience. They are not absorbed, followed, or accepted by more than ten per cent of an audience All medical meetings would go along more skilfully and with better results if these necessary, elaborate, and yet tiresome features were excluded It is quite essential that they appear in the article when published, but it is a sad blunder too long tolerated to have long analyses cluttering up an otherwise brilliant paper The end results in figures would be enough The other is never mentally accepted, so why use it?"

day and you are to be congratulated at having such an efficient executive body that they can give you so much at such a nominal expense The dues of this Association are the lowest of any Association in the United States giving Medical Defense

"We receive the benefits of the legislative program promulgated by it The splendid work of the Department of Public Health of the State in which it cooperates, aids us materially in our efforts to help humanity It is working industriously to establish hospital facilities in every county or group of counties and to improve those already established It carries Medical Defense protecting its membership and paying expenses in case of suit It is lending support to the splendid efforts of the Woman's Auxiliary in its development of an educational fund for the medical education of Georgia boys in medicine It gives you a Medical Journal of real scientific worth Through its Medical Relief in Disaster it presents an opportunity for you to aid the unfortunate It offers rare opportunities to its membership in the Crawford W Long Memorial Prize contest and in the Abner Welborn Calhoun Lectureship It affords opportunities for you to meet your fellow man in medicine and to discuss in an informal way matters of ... ical import Many more are the objectives ... this Association by which you are benefited b these few should illustrate its value to you

INDIANA BUREAU OF PUBLICITY

The newspaper releases by the Indiana Sta... Medical Association are appreciated by the people according to the following editorial in the July Journal

"The editor of one of the prominent daily newspapers in Indiana has informed us that he considers the bulletins issued by the Bureau of Publicity of the Indiana State Medical Association as containing more trustworthy and useful health education than anything that can be brought before lay readers At first he was skeptical as to the real reason for releasing such articles under the sponsorship of our Association, but after noting the releases week after week, and month after month, he says he has come to the conclusion that the Bulletins are very valuable for the public, and he takes pleasure in publishing them in his newspaper We also have heard various favorable comments from lay readers concerning appreciation of the bulletins of the Bureau of Publicity

IODINE IN SOUTH CAROLINA FOOD PRODUCTS

The July number of the *Journal of the South Carolina Medical Association* contains an article on the iodine content of foods grown in the state, and also the following editorial comment

"A wonderful meeting was held at Columbia, June 20, pursuant to a call of Dr F H McLeod of Florence for the purpose of discussing ways and means by which the medical profession could promote the publicity of the high iodine content of our home grown food products The *Journal* has consistently supported the idea to the effect that the medical profession should be the real leaders in this movement. The evidence appears to be sufficiently conclusive to warrant every doctor in South Carolina in getting solidly behind the whole profession both from a scientific and commercial standpoint Too often, scientific discoveries do not receive the full approbation of those who should be the first to acknowledge their value In this instance we are pleading for a speedy acknowledgment of a great opportunity to serve not only the state but the nation"

INSURANCE FOR DOCTORS IN SOUTH CAROLINA

The July issue of the *Journal of the South Carolina Medical Association* suggests a state-wide plan for the insurance of physicians as follows

"The State Medical Association as yet has not turned its attention toward one of the important phases of protection of its members in the form of health and liability insurance Group insurance offers protection at a much lower cost than is possible to the individual as was proven during the World War and by many organizations since that time This type of insurance may be applied to malpractice as well as life and health Commercial organizations have now perfected such insurance to the point where it is safe and very reasonable as to cost.

TRICHINOSIS—RECENT OBSERVATIONS*

By MARTIN WEISS, M D, BINGHAMTON, N Y

SINCE my recent publication of six cases of Trichinosis in one family[1], I have observed five others, three of which occurred in one family A rather careful and complete clinical study was made of one, and the observations obtained from this case brought out some apparently new and interesting findings The most important one of these was the finding of six encysted trichinae, reencysted in one large capsule, lodged between the striated fibres of the deltoid muscle near its tendenous insertion The biopsy was performed 19 days after the onset of the disease which showed a marked degree of encystment that had already taken place, together with other pathological changes in the field, which will be explained later on in this paper Another interesting observation was the repeated finding of the mature trichinae in large numbers in the stools for several weeks after the onset of the disease Photomicrographs are shown in figures 1-2-3 and 4

In presenting the series of cases I want to say something of this disease in general For convenience, we may divide this disease into three stages, all of these stages, or activities of the trichinae may occur at the same time.

1 Period of gastro-intestinal infestation
2 Period of dissemination
3 Period of encystment

The period of gastro-intestinal infestation occurs when under-cooked pork, ham, beef sausages and other meats infected with living encysted trichina spiralis are eaten By the heat of the gastro-intestinal tract, and the action of the gastric juices present, these encysted trichinae are liberated into the stomach and upper part of the duodenum, from their cysts, in an immature stage As one ounce of meat may contain as many as 100,000 trichina spiralis, and each female may give birth to several thousand we can readily understand the enormous infection that may occur from eating several ounces of trichinous meat Ransom has shown that a large proportion of encysted trichinae are killed at 55 degrees C (130 degrees F) For this reason it is very essential to cook all meat so thoroughly as to destroy the worms before ingesting

The trichinae when liberated from their cysts mature in the upper part of the small intestines in from 2 to 3 days The mature male is about one-sixteenth of an inch long and the female about one-tenth of an inch long Copulation and fertilization takes place in the small intestines The males are said to die off after copulation, but the life cycle of the female is about six weeks during which time she may liberate several thousand larvae This fertilized female trichina burrows herself into the mucosa of the small intestines about one-fifth of its length and the embryos escape from the vulva which is located in the anterior portion of the worm These larvae are taken up by the blood and lymph stream, and distributed to all portions of the human body, as they are smaller than a red blood cell The mature worms, I have found, may remain in the gastro-intestinal tract for many weeks

The symptoms observed during this period of gastro-intestinal infestation are fever, nausea, vomiting, diarrhea, abdominal pains, and general malaise These may be caused by the liberation of the trichinae and their toxins from their cysts, and also by the irritation of the intestinal wall caused by the burrowing of the female trichinae These symptoms may be mistaken for Typhoid Fever or Auto Intoxication

Children have a more sensitive gastro-intestinal system and therefore symptoms produced are more pronounced, the diarrhea being a great aid to lessen the severity of the disease, as a result of the expulsion of the worms The children may go on without the disease ever being recognized

Of my series of 11 cases, five of these were children, none of whom had oedema of the eyelids, nor severe muscular pains but did have gastro-intestinal symptoms The reason for the above might have been that either the children did not eat as much meat, or that their vomiting and diarrhea helped to get rid of the trichinae I may state that a vermifuge colonic irrigations, duodenal or gastric lavages are indicated at this

Charmingly located, beautifully appointed, in the hilly country one and a half miles from Long Island Sound where the air is tonic Quick drive from New York City Truly homelike, no institutional appearance.—See page xxxiii —*Adv*

ROBINSON'S "PATENT" BARLEY & GROATS

These two old established preparations have held the confidence of the Medical Profession for years. The Barley is mainly employed in infant dietetics, and for the quick preparation of pure Barley Water Robinson's Groats are largely recommended in conjunction with cow's milk for weaned infants, expectant and nursing mothers, and as an invalid diet.—See page xxi —*Adv*

AGAROL

Agarol contains no sugar—safe in diabetes, no alkali—does not interfere with digestion, no excess of oil—to cause leakage. Just the right proportion of ingredients to afford these desirable actions Softening of the intestinal contents, gentle stimulation of the peristalic function.—See page xxiii —*Adv*

MEAD'S DEXTRI-MALTOSE

Mead's Dextri-Maltose, cow's milk and water can, with but few exceptions, be relied upon for good results in artificial feeding cases

The addition of Dextri-Maltose makes up the carbohydrate deficiency in the cow's milk. It is easily assimilated—well tolerated.

Gains in weight are usually normal, presenting a healthy clinical picture—sound musculature—good color

There is a minimum of nutritional disturbances of a fermentative nature due to the greater assimilation limits of Dextri-Maltose over either lactose or sucrose.

Dextri-Maltose No 1 is indicated for normal infants, while the No. 3 with 3% addition of potassium bicarbonate, is the clinical choice if calcium constipation is present.—See pages xix —xxxvi —*Adv*

AURORA HEALTH FARM

A new addition to the AURORA HEALTH FARM has just been completed, and this time it is an altogether modern building with elevator service from basement to roof, private bath and telephone in each room, a large, sunny dining room overlooking a magnificent panoramic view of the surrounding hills, a beautiful big lobby with adjoining porches that invite relaxation, and amusements rooms for indoor games in general.

The purpose of this institution will continue to be the care and treatment

instances, as it was in the case that I am about to present, the worms are not found for several weeks after the onset of the disease, and then they may be repeatedly found in large numbers as seen in Figures 2 and 3

2 *Blood Picture* This also plays a very important role, as this together with a positive history of eating pork may be the only means of diagnosing the disease At the beginning, during the acute stages there may be a low eosinophile count, but as the disease progresses this may reach as high as 50% In one case I found it to go as high as 47% There is no relationship between the eosinophile count and the severity of the disease except that a sudden drop is said to be a bad omen In the case to be presented, the eosinophile count was only 4% on the third day of her illness, at a time when she was very ill

There is nearly always a rather high leucocytosis and an increase in lymphocytes, with diminution in polymorphonuclea leucocytes The

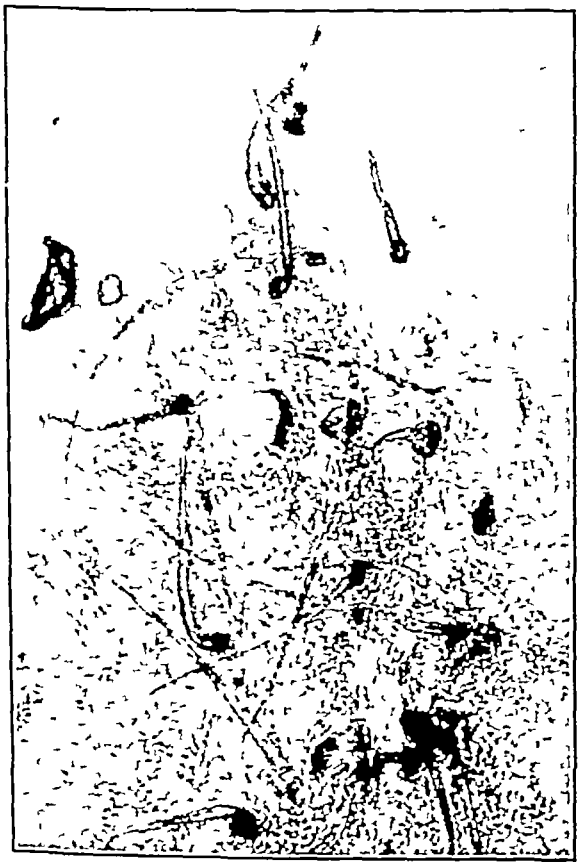

FIGURE 3
Trichina spiralis in intestinal tract Low power (X 33)

red blood cells, hemoglobin and color index are not altered much The larvae have been found in the blood stream

3 *Spinal Fluid* The spirilli have been found in the spinal fluid, and a lumbar puncture may be resorted to when other means of diagnosis fails, or when the patient is showing signs of cerebro spinal disturbance

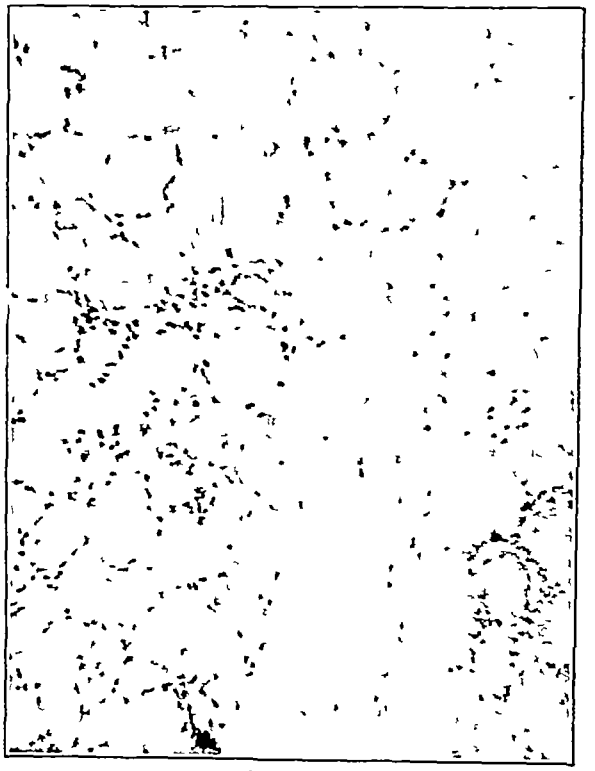

FIGURE 4
Myositis in deltoid muscle Case of Trichinosis

4 *Urine* No definite or permanent change can be found in the urine except that the Diazo Test, or Methyline Blue Test may be positive

5 *Temperature, Pulse and Respirations* During the first week the temperature rises gradually, or is slightly remittant It may reach 104 or 105 degrees, then remain high for about one week, and finally begin to recede at about the third week

The pulse is comparatively slow in relation to temperature The respirations are normal unless the respiratory muscles are affected by the invasion of the trichinae This chart gives us a picture almost similar to that of Typhoid Fever

Prognosis

Death rate 2-3%
Depends on the number of trichinae eaten.
Good in children on account of smaller amounts of meat eaten, their vomiting and diarrhea
Prognosis is poor when there is respiratory failure (occurs usually between the 4th to 6th week)
Prognosis is poor when there is a sudden drop in the eosinophile count

time so as to expel the worms that they may not enter their 2nd or 3rd stages

The second stage, or stage of dissemination of the larvae trichinae into the blood and lymph stream, is claimed by many to begin at about the end of the first week, but it is my belief that this occurs earlier in the disease on account of the fact that patients complain early of the symptoms produced by this stage, as oedema of the eyelids or face, or severe muscular pains These are caused by the parasitic infestation to those areas Because of the fact that mature trichinae exist in the intestines for several weeks, we still have the first stage going on with the second, and it is at this time when the patient presents the many symptoms of the disease

As I have stated before, the larvae are given out in large quantities into the blood and lymph stream and consequently to every available part of the body They have been found in every fluid, including the breast milk, with the exception of the urine Hassin and Diamond[2] have given a very splendid account of Trichinosis Encephalitis, death having been caused by the extensive invasion of the trichinae into the brain and surrounding tissues Trichinae make their habitat in the striated muscles where they enter their third stage or encystment This stage may accompany the other two and a multiplicity of symptoms be present

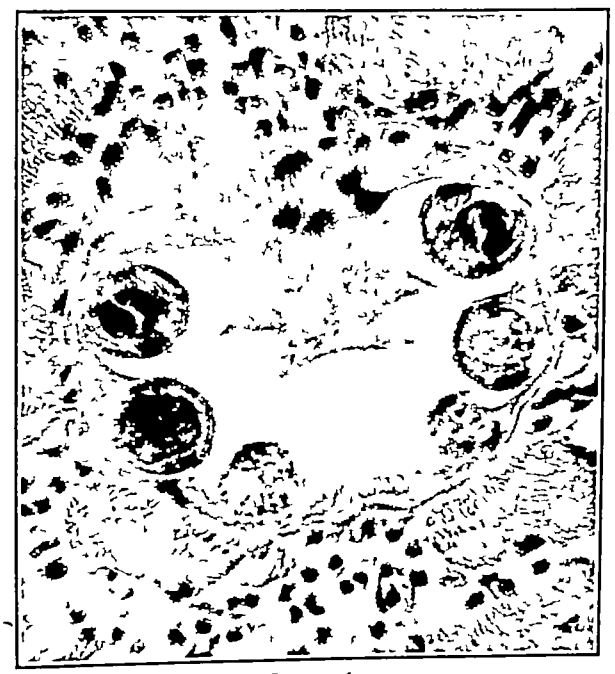

FIGURE 1

Encysted trichinæ in deltoid muscle High dry X 150

The third stage begins at about the third week, the larvae grow a little and then coil themselves in between the fibres of the striated muscles and form a capsule made of their own excretions Later on this capsule, which is formed from the destruction of the muscle fibres, becomes calcified

FIGURE 2

Trichina spiralis in intestinal tract High power dry lens (X 150)

The trichinae continue to live in their cysts for many years (20-30) Figure 1 shows the degree of encystment that takes place 19 days after the onset of the disease The encysted trichinae are most commonly found in the deltoid, gastrocnemi, diaphragm, intercostal and tongue muscles In the long muscles, the best place to find them would be near their tendenous insertions

It is in this stage that pathological changes occur in and around the muscle fibres, as well as in the blood and cerebro spinal system Some of these pathological changes are myositis, small round cell infiltration, increase intracellular tissue calcification of the cyst wall, destruction of muscle fibres and encephalitic changes, as seen in Fig 4

H A Williams of Buffalo has found that on doing 505 autopsies on persons dying of diseases other than Trichinosis encysted trichinae spirilli were present in 53% of the cases This again proves that a great many people have the disease so mildly that it goes on without any recognition of its presence

CLINICAL FINDINGS

1 *Stools* The finding of the trichinae in the stools makes the diagnosis positive Repeated examinations should be resorted to, because in many

THE CANCER SITUATION IN THE STATE OF NEW YORK

V The Cancer Clinic

By JOHN M SWAN, M.D, F.A.C.S, ROCHESTER, N Y
From the New York State Committee of the American Society for the Control of Cancer

ONE of the methods approved by the American Society for the Control of Cancer as of value in its attack on the cancer problem is the establishment of cancer clinics In its publication entitled, "Cancer Clinics and Consultation Services," the Society suggests that the clinics may be temporary or permanent General suggestions are made for the establishment of both kinds of clinics The Society is mindful of the fact that in different parts of the country local conditions may make it desirable that certain modifications be made in the methods suggested for the organization of both types of clinic

The experience of the New York State Committee has been that when the members of the organized medical profession are questioned about the advisability of the establishment of cancer clinics several objections are made

Some physicians say that there are already plenty of clinics established to which people may go for diagnosis and advice as to treatment Other physicians have said that people would not go to cancer clinics Still others have said that the establishment of such a clinic would serve to frighten people and prevent them from asking advice which they otherwise might request Still another group says that cancer is a hopeless condition in regard to which there is no use in raising hopes that may prove futile

In the summer of 1924 the New York State Committee, after considerable deliberation, concluded that it might be useful to establish a cancer clinic in one of the larger communities in the state as an experiment, in order to determine the correctness or falsity of the opinions above mentioned In view of the fact that the chairman of the State Committee the chairman of the 7th District Committee and the chairman of the Monroe County Committee had their residences in the City of Rochester, it was determined to undertake the establishment of such a clinic in that city

It was decided, first, that the clinic should be conducted as a diagnostic and advisory enterprise and that no treatment should be given Second, that the clinic should be operated in cooperation with the practicing physicians in the city of Rochester and that every person seeking advice should be referred back to his regular medical advisor, in an endeavor to build up confidence between the patient and the physician Third, that the clinic should be operated as an item in the educational program adopted by the Committee in carrying out the policies of the National Society

The staff was organized to consist of two general surgeons, two gynecologists two internists, a laryngologist, a dentist, a dermatologist, and a radiologist A registered nurse was employed to act as secretary of the clinic and a practical nurse was also employed with the view of instructing her, and through her, the people with whom she would come in contact, with the object of breaking down some of the objections on the part of lay people to listen to a discussion of the cancer problem

The Clinic was opened on July 14, 1924, and as a result of four and a half years of operation, the clinic staff feels that it is able to say positively first, that people will go to a cancer clinic, second, that they want to know whether or not they have cancer, third, that the operation of the clinic, so far as its staff is able to determine, is not a source of cancerphobia, fourth, that some physicians refer their patients for opinion and advice

The operation of the clinic is not designed to take people away from their family physicians, nor to compete with the out-patient clinics of the hospitals of the city; but rather to act as a cooperative body both for the practicing physicians and the hospital clinics

A man may think that he has symptoms that indicate cancer of the stomach He goes to his family physician or to a general medical clinic where he is examined and an opinion given, but during the examination the patient does not say to the physician who is studying his case, "Is my trouble cancer?" The physician has no means of knowing that the patient thinks his trouble may be indicative of cancer and, consequently, makes no statement to the effect that the disease is or is not of a malignant nature As a result, the patient goes away from the physician's office or from the clinic with his question unanswered On the other hand, as soon as a patient appears at a cancer clinic, the physicians who examine him know that he thinks he has cancer Very frequently the nature of the disease is so evident that it is possible to assure him at once that his trouble is not due to cancer, with consequent relief of mental anxiety and worry Each patient is commended for his interest in his health which brought him to the clinic It is pointed out emphatically that cancer is never painful in its early stage and that annual physical examinations are most important for this reason Literature of the American Society for the Control of Cancer is distributed.

Personally, I should like to see every hospital in the territory of the New York State Committee which now has an out-patient department or in which an out-patient department may be established in the future, conduct a cancer clinic as often as the local conditions warrant

Treatment

1 The prophylactic precautions taken in cooking all meats well is very important
2 Daily high saline colonic irrigations
3 Daily injections of 1 gr Thymol in 1 c c of sterile olive oil injected intramuscularly for seven days (this has not shown me any convincing results)
4 Gastric or duodenal lavage as described by Dr Rivas[3] seems to give striking results
5 Symptomatic treatment

Report of a Case

On October 10, 1928, Mrs K, age 32, together with her husband and a daughter 8 years of age, ate a dinner consisting of roast pork That evening they had some more of the meat The following morning she took to work two sandwiches of pork, but ate only one because she felt weak, dizzy, and had pains in her epigastrium She vomited once and was then compelled to leave her work The next morning, second day of the disease, she was unable to open her eyes due to the generalized facial oedema An ophthalmological examination revealed no pathology except a slight conjunctivitis Headache was severe and she vomited several times She acted drowsy, was slow in speech and ataxic in gait She presented a picture of a drunken person

On October 13 (third day of illness) she was unable to stand on her feet on account of weakness and pains in her calf muscles The oedema of her eyes was slightly improved, while in other parts of her body it increased, vomiting persisted, and her bowels moved only with the aid of an enema On the same day she was admitted to the hospital with a temperature of 102 degrees, and a pulse of 90 A blood count revealed 15,800 leucocytes, 74% polymorphoneuclears, 17% lymphocytes, 5% large mononeuclears, 4% eosinophiles, 83% hemoglobin and a red blood count of 4,800,000

On the following day the other two members of her family were admitted to the hospital with gastro-intestinal complaints, grippy pains and malaise.

Blood counts showed a leucocytosis with a 26% eosinophile count for the girl and a 6% for the father The diagnosis of trichinosis at this time seemed probable

As the disease progressed, the oedema which was general, slowly subsided, but the muscle pains became more pronounced, extending to her thighs, upper arms, pectoral, intercostal and abdominal muscles Headache was severe, cough dyspnea, chest and upper abdominal (diaphragmatic) pains were her chief complaints at the end of the first week A Roentgenoscopic Examination of her chest did not show any pathology at this period Her condition slowly improved during the stay of 35 days in the hospital and she was discharged on Nov 17, 1928, weak

The oedema of her eyelids, together with several of her other symptoms and complaints reappeared in a milder form during her illness This was the result of a new invasion of the Trichinae into her system

Clinical Findings

1 Urine examination gave a positive Diazo reaction, otherwise it was negative
2 Stool examination was positive for Trichinae Spiralis on Oct 24 (13th day of her illness), after many previous negative examinations They remained positive for several weeks Figures 2 and 3 show the trichinae in one of the specimens The stools remained positive for about three months
3 Blood Fifteen complete blood counts were done at intervals of a few days, all of which showed an increase in the leucocytes and eosinophiles, with a relative decrease in polymorphoneuclears and lymphocytes The red blood counts and hemoglobin were either normal or slightly increased
4 Spinal fluid was negative for the trichinae on two examinations done at a four-week interval
5 Biopsy of a piece of the deltoid muscle near its tendinous portion was performed on Oct 30, 1928 (19th day of illness) and six encysted trichinae were found Figures 1 and 4 show not only the trichinae but also the pathological changes that existed at that stage of the disease
6 Temperature, pulse and respirations were somewhat similar to what is found in Typhoid Fever

Conclusions

Gastro-intestinal complaints, oedema of the eyes and muscular pains are pathognomonic

There is no definite ratio between the leucocyte count and the eosinophile count, and the eosinophile count is no index to the severity of the disease

During the acute stage a low eosinophile count may be present

Trichinae Spiralis may be found in the stools many weeks after the onset of the disease

place on account of illness The same day Dr Abramowitz, Health Officer of the town of Thompson, with whom Dr Duggan had already communicated, telephoned that he had located the cook in his district He stated that he believed the woman to be suffering from typical typhoid

The same day a letter was received from the Department of Health of the City of New York stating that a fatal case of typhoid had occurred in a Yonkers man, another case had been reported in a Brooklyn man, and that a rumor had been received that two other cases had occurred, —all in people who had spent Decoration Day at the X Hotel

A conclusion which might have been jumped at (but it wasn't) was that a cook with typhoid had communicated the disease to the proprietor's son and the boarders Looks good, doesn't it?

But, consider the *dates of onset,* something we have harped about until we assume everyone is tired of hearing it

Inquiry showed that the cook and the proprietor's son became ill *at about the same time, June* 15

The onsets of the cases among the boarders were from June 9 to June 17 Therefore, we are justified in concluding that the proprietor's son, the cook, and the boarders had a *common source*

The Evidence—The boarders who contracted typhoid had been at the X Hotel from May 29 to June 2, and one had stayed until June 10 Taking into consideration the period of incubation of typhoid, it is evident that the infection in all the cases must have been received during the Decoration Day period,—2 or 3 days before and after May 30 We are, therefore, concerned with evidence pertaining to that period *only*

We know that the source must have been either water or milk or other food

The water continued the same before, during, and after the period in which we are interested, and is still the same. The last case had its onset June 17, and there have been no more We therefore tentatively exclude water

The regular milk supply was the same as that supplied to other hotels in the vicinity, in which no typhoid occurred. We therefore exclude it.

But there was an auxiliary supply, 3 or 4 quarts daily obtained from a nearby farm during the Decoration Day period A new milk handler had just been employed This gave us some concern *But the sale of milk had been continued* from this farm, with no change of personnel, up to July 5, with no cases and there have been none since then We therefore tentatively exclude it

Food and Specifically, Food Handlers—During the Decoration Day period, the food handlers consisted of

1 People belonging to the family
2 Those first employed at that time

We exclude the first group because typhoid had not occurred at the X Hotel in previous years

In the second group were a girl and three men.

We exclude the cook for obvious reasons

We tentatively exclude the three men, partly because their connection with the food was not very close, but principally because they continued at the hotel and no cases occurred afterward

This leaves us the girl She was in close contact with food, one of her duties being the preparation of salads, a process we ascertained, in which the ingredients were freely handled The girl was not well, but had a "weak stomach," which is always suspicious Her work was not satisfactory and she was dismissed two or three days after Decoration Day But where she had gone was not known at the hotel *We needed that girl*

It was ascertained that she had been employed through a local employment agency We tried to secure information from this agency last year, and "remonstrated" with the proprietor for the lack of records We told the proprietor this time that we didn't expect anything Our bluff was promptly "called" by the production of most valuable information It appeared that on June 4 the girl had returned to the agency, and had secured a position as chambermaid in another hotel

Dr Harry Jacobs, health officer of the town of Fallsburg, in whose district this latter hotel was located, was asked to secure the necessary specimens This was promptly done, and the State Laboratory reported the demonstration of typhoid bacilli The girl was a typhoid carrier, and the source of the outbreak

It is to be noted that, by elimination, we reduced the possible sources to *one* hypothesis,—the girl The elimination necessarily could not be absolute in all of the instances, but we selected as our first hypothesis to be proved or disproved, the "most likely" one

Dr Slee the District State Health Officer of the East Hudson District, visited the carrier, secured the facts relating to her previous history, and arranged that her work should not include the handling of food However, she soon left for parts unknown The New York City authorities were notified, and we have before us a copy of a letter stating that the girl is again under the control of health authorities

The first 500 patients who appeared at the clinic presented the following conditions

I	*Malignant Neoplasms*			90—18 0%
	A Carcinoma		40	
	Breast	25		
	Jaw	1		
	Larynx	1		
	Penis	1		
	Rectum	2		
	Stomach	3		
	Tonsil	1		
	Uterus	6		
	B Epithelioma		39	
	Cervix	2		
	Lip	5		
	Skin	30		
	Tonsil	1		
	Vulva	1		
	C *Carcinoma (suspect)		11	
	Breast	1		
	Cecum	1		
	Cervix	1		
	Colon	2		
	Rectum	2		
	Stomach	4		
II	*Benign Neoplasms*			65—13 0%
	Angioma		8	
	Cysts			
	Lip		1	
	Mammary		1	
	Nabothian		1	
	Sebaceous		19	
	Thyroglossal		1	
	Epithelial hypertrophy		2	
	Fibroadenoma		2	
	Fibrolipoma		1	
	Fibroma		10	
	Keloid		2	
	Lipoma		13	
	Osteoma		1	
	Papilloma		3	
III	*Precancerous Lesions*			97—19 4%
	Biliary tract disease		1	
	Cervical laceration		2	
	Cervical ulceration		2	
	Cervicitis		2	
	Cholecystitis		6	
	Endocervicitis		4	
	Gastric neurosis		4	
	Hematuria		1	
	Hemorrhoids		9	
	Keratosis		23	
	Leukorrhea		1	
	Mastitis, chronic		18	
	Chronic cystic		4	
	Nasal ulcer		2	
	Peptic ulcer		6	
	Pigmented mole		9	
	Prostatic hypertrophy		2	
	Rectal ulcer		1	
IV	Benign Skin Lesions			32
V	Nervous Diseases			28
VI	Gynecological Diseases			27
VII	Gastrointestinal Diseases			31
VIII	Cardiorenal Diseases			11
IX	Respiratory Diseases			2
X	Endocrine Diseases			14
XI	Miscellaneous Conditions			103
	Of these, 21 had no demonstrable disease and three had been operated at a former time, but showed no evidence of recurrence			

* Suspected cases are counted as positive

Clinics similar in character to the Rochester Clinic are conducted at the Samaritan Hospital and the Troy Hospital in Troy The Medical School of the University of Rochester conducts a tumor clinic once a week, and the Albany General Hospital holds a radium clinic twice a week in cooperation with the Albany Medical College

The Buffalo City Hospital has just announced the establishment of a cancer clinic The New York State Institute for the Study of Malignant Disease, in Buffalo, has conducted clinics and maintained a hospital for suitable cases for such a long time that it sees about 1 500 cases of cancer and suspected cancer every year

PRACTICAL EPIDEMIOLOGY

By FRANK W LAIDLAW, M D, MIDDLETOWN, N Y

From a mimeographed Bulletin of Dr Laidlaw s District State Health Officer District

WE WISH to ask every Health Officer and Public Health Nurse in the district to read carefully the following example of an analysis and the teamwork which led to the solution of a typhoid problem

July 3, Dr Duggan, Health Officer of the town of Bethel, Sullivan County, telephoned the Middletown office that the son of the proprietor of the X Hotel had typhoid, and that he understood that the cook employed at the hotel had left the

fied with the environment. They are acquainted with the roads and people and generally familiar with conditions in the various communities and of lay organizations which knowledge may be a distinct asset to the County Health Department It has a tendency also to lessen the criticism concerning "foreigners" which sometimes arises If Civil Service has been adopted by the county the examination should be restricted to residents of the county

In selecting other professional personnel, preference to residents of the county should be given if suitably qualified, but residence should be secondary to ability and experience in the performance of the required duties Additional members should be added to the staff of the County Health Department as the needs and growth of the work indicate, but haste should be avoided as it is much more liable to cause criticism than tardiness, and we are less apt to find it necessary to change our methods to meet a program which further study of health needs may indicate.

The organization of his office will be the next concern of the Health Officer The recording of all work performed is of the utmost importance and suitable forms and equipment for a proficient filing system are the sine qua non of any health department It is surprising the number of references to files which become necessary as your department progresses and clerical records of accomplishment often astonish one

As the County Health Department is an official part of the County government, the offices should be at the County Seat, and suitable office space and equipment be provided by the Board of Supervisors To forestall criticism of this assertion, I will say that while I am aware that the County Seat is not always located so as to be the most accessible to the center of population of the county, that it may not be the most desirable place to live, and that such location may entail the establishment of a sub-office, nevertheless, the added prestige given to the Department when located in the Court House, the fact that it is more readily accepted by the other county officials as an integral part of the County government when so located, and consequently receive better cooperation from them, far outweigh all other considerations

The first duty of the Health Officer is to journey around the county and to get in immediate personal touch with all local health officers and physicians Following this, he ought to make as many contacts with other health and social workers as it is possible for him to do, and with all civic organizations He should at the earliest opportunity become a member of the County Medical Society and such other organizations as exist in his county and district and familiarize himself with the clinical and hospital facilities in his territory

He should determine what other organizations are engaged in some form of public health work, their scope, their character, whether official or voluntary, and desirability of assuming some of these functions or of co-ordinating the program of the County Health Department with already successfully operating services, and should familiarize himself with facilities available in allied welfare work from whom he may require or to whom he may be asked to give assistance in solving problems having a health angle.

Social service in Suffolk County is well organized The Child Welfare Board is an official county organization caring for dependent, delinquent or defective children and giving assistance to widows or dependent mothers, and with the passage by the recent Legislature of the Fearon Bill with reference to public welfare, adequate hospital and medical care will be possible for the indigent sick We have also several local social service organizations for case finding in welfare work The needs of the physically handicapped will be met by the operation of the recently enacted legislation providing aid through the Department of Education as well as the orthopedic service of the State Department of Health Able assistance is given by the Tuberculosis and Public Health Committee through its nurses and secretary in both practical assistance and in public health education

In most County Health Departments it will be wise after making this survey to concentrate on some outstanding problem for a year or two, not however in any way neglecting routine duties In Suffolk County we are concentrating on the sanitary production of milk as one need and the building up of local nursing service as another

Routine duties common to all health departments are

1 Communicable Disease control
2 Laboratory service
3 Tuberculosis control
4 Maternal and infancy hygiene
5 Preschool and school hygiene
6 Investigation and abatement of nuisances
7 Supervision of water and milk supplies
8 Disposal of sewage

Communicable disease control in the main is taken care of by the local deputies of the County Health Officer with the assistance of the school medical inspector and nurses Epidemological investigations are made by the County Health Officer Under the recently amended County Health Law increased authority is given the County Health Department and in Suffolk County the former township health officers are acting as deputies covering the entire township area inclusive of incorporated villages having a population of less than 3,000 There are townships varying in population from 1,100 to 28,000 and six incorporated villages having a population

A COUNTY HEALTH DEPARTMENT IN OPERATION

By ARTHUR T DAVIS, M D, RIVERHEAD, N Y
County Health Officer, Suffolk County

IN considering the operation of a County Health Department we ought first to review the reasons leading to the establishment of units on a County basis

In the South where County Health Departments have had the greatest growth, the unit of government is the County, whereas in the North it is the Township, so originally boards of health were established along the lines of local government, and, when the chief functions of boards of health and health officers were contagious disease control and abatement of nuisances, the part time local health organization was sufficient for these elementary needs, but with the increase in knowledge both of scientific medicine and other means of prevention, it was realized that many other factors, both social and economic, entered into the public health picture It must be further realized that, while the medical profession is generally accepted as the preponderant force for public health progress, there are others who have a great interest in community health,—the welfare organizations, educational authorities, industry and the public in general are involved,—and the cooperation of all is essential to the solution of the many problems of public health

As health problems increased the medical profession sought and received the aid of the engineer, laboratory worker, the public health nurse and others in overcoming those diseases which are controlled and prevented as a result of community effort The natural result was the addition of one duty after another by legislatures to both local health officers and State Health Departments, until the local health officer could no longer give to his public health work the amount of time required as this must always be secondary to private practice of medicine on which he is dependent for his livelihood This led to the increase in personnel and authority in the central bureaus to assist and direct purely local problems In many states part time county health officers were appointed, in others the State Health Department has sought to remedy matters by District Health Officers, but neither plan gives entire satisfaction It involves delay, long and arduous travel, extra expense and the bugaboo of dual authority So as time went on instead of increasing centralized authority, State Health Departments sought to decentralize, to decrease the amount of local work done by the bureaus and divisions and to increase local effort The logical outcome was to seek a unit of government sufficiently large and financially able to support an adequate health organization on a full time basis, and as few townships are able to do so, the County has become recognized as the logical unit of local health administration

Assuming then that the County Health Department is the best method found to date for public health administration, how does one operate?

This will depend largely on the geographic location, the budget, the number of personnel and the existence of other health organizations in the County If located in the so-called poor counties, it may consist of only a health officer, in others we find all variations up to an organization as it exists in Los Angeles County, California, which has a larger personnel and budget than most State Health Departments

In our own State two County Health Departments have been organized, neither of which will, at the present time at least, function in exactly the same manner, but owing to many differences will probably operate along different lines to accomplish the same results

These Departments are operating in Counties which are dissimilar in many respects Cattaraugus has within its trea two cities, Suffolk none. Cattaraugus is largely rural in the sense that it consists largely of farming area, while Suffolk has many small communities which are suburban in character Cattaraugus has a relatively fixed population, but in Suffolk the population is greatly increased during the vacation season, due to the vast number who enjoy its recreational advantages along the North and South shores, and its nearness to New York City brings a large transient motoring population throughout the summer season Even the climate is different, winter being very mild in Suffolk County and severe in Cattaraugus, making travel in the latter much more difficult in winter

The type of organization adopted by these two counties has been made to meet these various differences, and as most counties in New York State resemble either one or the other of these two counties, the plan of organization in use in one can be adapted to the needs of such other County Health Departments as may be organized

When the Board of Health has been appointed by the Board of Supervisors, they should first appoint the County Health Officer who must be appointed from an eligible Civil Service list, thereby insuring proper training and experience in public health administration. Other personnel ought not to be chosen until the County Health Officer is on duty as all other appointments should be made by the Board on his recommendation

In selecting personnel, it is desirable to secure the clerical force and such inspectors as may be employed from among the residents of the county This is advisable because they are generally better qualified to know the many local customs It is their home and they will be satis-

fied with the environment. They are acquainted with the roads and people and generally familiar with conditions in the various communities and of lay organizations which knowledge may be a distinct asset to the County Health Department It has a tendency also to lessen the criticism concerning "foreigners" which sometimes arises If Civil Service has been adopted by the county the examination should be restricted to residents of the county

In selecting other professional personnel, preference to residents of the county should be given if suitably qualified, but residence should be secondary to ability and experience in the performance of the required duties Additional members should be added to the staff of the County Health Department as the needs and growth of the work indicate, but haste should be avoided as it is much more liable to cause criticism than tardiness, and we are less apt to find it necessary to change our methods to meet a program which further study of health needs may indicate.

The organization of his office will be the next concern of the Health Officer The recording of all work performed is of the utmost importance and suitable forms and equipment for a proficient filing system are the sine qua non of any health department It is surprising the number of references to files which become necessary as your department progresses and clerical records of accomplishment often astonish one

As the County Health Department is an official part of the County government, the offices should be at the County Seat, and suitable office space and equipment be provided by the Board of Supervisors To forestall criticism of this assertion, I will say that while I am aware that the County Seat is not always located so as to be the most accessible to the center of population of the county, that it may not be the most desirable place to live, and that such location may entail the establishment of a sub-office, nevertheless, the added prestige given to the Department when located in the Court House, the fact that it is more readily accepted by the other county officials as an integral part of the County government when so located, and consequently receive better cooperation from them, far outweigh all other considerations

The first duty of the Health Officer is to journey around the county and to get in immediate personal touch with all local health officers and physicians Following this, he ought to make as many contacts with other health and social workers as it is possible for him to do, and with all civic organizations He should at the earliest opportunity become a member of the County Medical Society and such other organizations as exist in his county and district and familiarize himself with the clinical and hospital facilities in his territory

He should determine what other organizations are engaged in some form of public health work, their scope, their character, whether official or voluntary, and desirability of assuming some of these functions or of co-ordinating the program of the County Health Department with already successfully operating services, and should familiarize himself with facilities available in allied welfare work from whom he may require or to whom he may be asked to give assistance in solving problems having a health angle

Social service in Suffolk County is well organized The Child Welfare Board is an official county organization caring for dependent, delinquent or defective children and giving assistance to widows or dependent mothers, and with the passage by the recent Legislature of the Fearon Bill with reference to public welfare, adequate hospital and medical care will be possible for the indigent sick We have also several local social service organizations for case finding in welfare work The needs of the physically handicapped will be met by the operation of the recently enacted legislation providing aid through the Department of Education as well as the orthopedic service of the State Department of Health Able assistance is given by the Tuberculosis and Public Health Committee through its nurses and secretary in both practical assistance and in public health education

In most County Health Departments it will be wise after making this survey to concentrate on some outstanding problem for a year or two, not however in any way neglecting routine duties In Suffolk County we are concentrating on the sanitary production of milk as one need and the building up of local nursing service as another

Routine duties common to all health departments are

1 Communicable Disease control
2 Laboratory service
3 Tuberculosis control
4 Maternal and infancy hygiene
5 Preschool and school hygiene
6 Investigation and abatement of nuisances
7 Supervision of water and milk supplies
8 Disposal of sewage.

Communicable disease control in the main is taken care of by the local deputies of the County Health Officer with the assistance of the school medical inspector and nurses Epidemological investigations are made by the County Health Officer Under the recently amended County Health Law increased authority is given the County Health Department and in Suffolk County the former township health officers are acting as deputies covering the entire township area inclusive of incorporated villages having a population of less than 3,000 There are townships varying in population from 1,100 to 28,000 and six incorporated villages having a population

of more than 3,000 This makes a very satisfactory arrangement as these village health boards are now under the direct control and direction of the County Health Board with no conflicting authority as formerly Adequate reporting of communicable diseases is of course dependent on the practicing physician, and frequent contact with them in medical meetings and elsewhere is a great help in securing early and accurate reports

Suffolk County is fortunate in having a Tuberculosis Sanatorium established in 1916, the staff of which conducts diagnostic tuberculosis clinics at frequent intervals throughout the county and provision is made for the employment of two nurses for follow-up work supported by the county funds The Tuberculosis and Public Health Committee also has two nurses who are assisting in this work and are doing some generalized nursing also All have assisted in diphtheria prevention campaigns and cancer campaigns

In both communicable disease and tuberculosis control, laboratory diagnosis is an essential factor, so that the advisability of adequate laboratory services is of major importance In Suffolk County we are accessible to the New York State Department of Health Branch Laboratory in New York City from which we receive excellent service, and in addition each of the four hospitals situated in the county maintains a laboratory with trained technicians for the use of the hospital staff These hospitals are strategically located, one at Bay Shore and one at Southampton on the south shore, and one at Huntington and one at Greenport on the north shore Another is nearing completion at Port Jefferson, also on the north shore which will have a well equipped laboratory Practically all the physicians in the county are connected with one or more of these hospitals The County Health Department plans a small laboratory for the examination of milk, water, sewage, etc, to meet the needs of its own personnel We therefore feel that adequate laboratory and hospital facilities are available for the people in better proportions than in most counties

For maternal care we are fortunate in the provision of adequate beds for maternity cases and the increasing use of hospital facilities by prospective mothers The county has a relatively small alien population, and consequently only a small number of births are attended by midwives The general economic status of the people is probably above the average

In infant and pre-school hygiene we have in operation several local centres supported by the community and with local physicians generously giving their services A careful study of the further needs of the county in this direction is being made and the best way of meeting these needs has not yet been determined In the meantime an occasional round-up of infants and preschool children is being undertaken

School hygiene is, as elsewhere in the State, under the direction of the Department of Education In Suffolk we have medical inspectors for all schools and practically all the large schools have full time school nurses In other instances several have combined to employ a nurse In others, community nurses do school service as a part of a general nursing service School physicians and nurses are co-operating heartily with the County Health Department and the Supervising Nurse acts for the Department of Education in the county to supervise and assists the school nurses

With reference to Public Health Nursing in Suffolk, we have school nurses We have Tuberculosis nurses, nurses employed by the insurance companies both full and part time and Red Cross nurses, the Tuberculosis and Public Health Committee has two nurses, several townships and villages are supporting community nurses doing public health and bedside nursing So it would seem that our problem would be to co-ordinate these existing agencies and to encourage additional community service where needed, so that at the present time we are employing only one Supervising Nurse, to do supervisory and organization work to bring this about Happily we are meeting with a considerable degree of success In many other counties it is more than likely that all full time nurses to be paid by the County Health Department and engaged in a generalized program would be of a more desirable plan

With reference to sanitation local health officers are to be relieved of nuisance investigation and abatement as this function will be taken care of by the County Health Department

The problem of waste disposal is an acute one in Suffolk County and is receiving careful study by the County Board of Health Owing to the very rapid growth of the county, the large number of summer residents and the small sized lots of many real estate developments, we are seriously concerned for fear our water supply, both public and private, may become polluted as these supplies are practically all from wells, there being at present only one surface supply in the county Sanitation of well areas is therefore vitally necessary

Sewage disposal is becoming a very important factor in our program Most disposal is by cesspool and with the small size of the lots there is grave danger in this method of the owner polluting his own well, as deep wells are apt to be brackish and shallow wells are theretore the rule. Sewerage systems are not as fully utilized as they should be, and it will be our aim to encourage the formation of sewer districts

The garbage dump and refuse pile are other forms of potential nuisances which are receiving

consideration and the building of incinerators for inflammable refuse, garbage and dead animals is receiving attention by several of the large townships, the Town of Huntington having already shown leadership in the erection of a most excellent plant.

In sanitation of milk supplies we have a unique position in the State as the Board of Supervisors have appropriated additional money to the County Health Department for the services of a Veterinarian Practically all milk produced within the county is consumed locally, so that Tuberculosis eradication in cattle is in fact essentially a health measure which will be of benefit solely to the residents of Suffolk County The Supervisors recognizing this fact have not created a separate commission but have made this a responsibility of the County Board of Health

The Veterinarian will also assist in the prevention of other diseases of cattle which may be transmitted to man, especially rabies, undulant fever and septic sore throat

In addition he will assist in food supervision, as it relates to meat, by endeavoring to secure the inspection of all meat killed locally for consumption in the County, this service to be paid for by the Town boards Two of the ten townships already have this service and several more are ready to establish such inspection

As a further factor in the program of milk sanitation we have a full time dairy inspector who is engaged in regularly visiting all dairies producing milk and already a great degree of improvement is manifest, both in equipment and method All permits will be issued by the County Board of Health and this will do away with the confusion of authority between village, town and county He also collects the milk for bacteriological examination Pasteurizing plants are under the supervision of the Sanitary Engineer

It seems to us that with the combination of Sanitary Engineer for the correction of defects in sanitation, a veterinarian for animal disease control, a dairy inspector for frequent check-up of method and equipment and the laboratory for bacteriological examination, a most excellent milk supply should result

One of the most important functions of the County Health Department is that of public health education In this we have only made a beginning

There has been published for some time the monthly News Letter which is the official organ of the County Medical Society and the allied health and welfare organizations to which the County Health Department is a contributor In addition, newspaper articles are being published which is, after all, the best way of reaching the mass of people. Lectures and talks are given and moving pictures on health are shown to Parent-Teachers' Associations, Mothers' Clubs, Women's Clubs, Civic organizations and all who ask for such services It is hoped later to issue a monthly bulletin of our own as well as special bulletins in health subjects

Finally, what are the advantages of a County Health Department? They are, briefly, those of any well directed business organization

Centralization of authority in one board instead of thirty-six as formerly in Suffolk County, with consequent elimination of conflicting authority between townships and villages

Availability of expert professional personnel beyond the ability of a single township to finance giving full time service in all branches of Public Health administration.

More and better service for the same expenditure of money

State aid to county up to one half the cost

An organization unit for prevention and a continuous program for the entire county with special emphasis on problems requiring community efforts

An organized unit for the prevention and suppression of epidemics of disease

An official central organization for the correlation of all health activities

---

DIAGNOSTIC VALUE OF LATENT JAUNDICE IN ABDOMINAL AFFECTIONS*

By HENRY A. RAFSKY, M D, NEW YORK, N Y

THE recognition of Jaundice, especially in the early stages, has always been of diagnostic value Until recently, the clinical and laboratory methods at our disposal did not always enable us to detect early signs of icterus However, with the development of the various tests for jaundice, the problem of recognizing minor degrees of icterus has been somewhat simplified

Jaundice is thought to be brought about by either an obstruction of some part of the bile passages with a reabsorption into the blood of the bile pigment previously excreted by the liver, or by a disturbance of the metabolism of the bile pigment which results in a retention of the pigment

A certain amount of bile pigment is known to be present normally in the blood plasma and the greater part of this pigment is bilirubin Under normal conditions this is rapidly

* From the Gastro-Enterological Clinic, Lenox Hill Hospital New York.

removed from the blood stream by the liver If the amount of pigment in the blood stream is greater than is readily taken care of by the excretory organs, it may accumulate in the plasma and jaundice result

It has been definitely shown that an increased amount of bilirubin in the blood (Hyperbiliruminemia) can be detected in the serum before there is any other clinical manifestation of jaundice Therefore, the estimation of the amount of pigment in the blood enables us to differentiate between "apparent" and "latent" jaundice

"Apparent Jaundice" is a term that is applied to the clinical picture of hyperbiliruminemia, increased output of bile in urine, lessened bile content in the feces, and discoloration of the skin and conjunctiva "Latent Jaundice" is a term applied where the retention of bilirubin can be detected only in the blood and there is no other clinical manifestation of jaundice

The subject of latent jaundice was studied in 158 cases It was found that the original icterus index of Muelengracht, modified by Bernhard and Maue as suggested by Stetten[1] was best suited for this purpose This is essentially the method that was adopted by Bernheim[2] Shattuck[3] stated that the icterus index was the most useful functional liver test for clinical work He regards the normal icterus index between 3-6, the latent jaundice between 6-15

The cases were studied with a twofold purpose first, to ascertain to what extent the determination of the bilirubinemia in latent jaundice aided in the diagnosis of abdominal affections, secondly, to determine if latent jaundice had a distinct time relation to the onset of pain in biliary colic

The patients selected for study were those who complained of at least a moderate amount of abdominal pain and who did not have any clinical signs of jaundice The blood was examined as soon as possible after an attack of abdominal pain

The cases studied were as follows Cholelithiasis 26, Cholecystitis without stones 39, Gastric Ulcer 8, Duodenal Ulcer 14, Functional Hyperchlorlydria 21, Cardiopsasm 2, Carcinoma of Oesophagus 2, Carcinoma of Stomach 3, Chronic Appendicitis 6, Colitis 7, Visceroptosis 10, Chronic Gastritis 4, Chronic Enteritis 5, Habitual Constipation 3, Post Operative Adhensions 8

Sixty-five cases of gall bladder affections were studied In forty of these patients, whose blood was examined from 1-20 hours after an attack of abdominal pain, the icterus index varied between 8-12, latent jaundice being present in 85 per cent of these cases One patient had an icterus index of 25, without the slightest evidence of apparent jaundice In the remaining 14 per cent of the cases the icterus index varied between 3 5-6

In twenty-five cases of gall bladder affection, where the blood was examined between attacks of abdominal pain or more than 20 hours after its onset, the icterus index varied between 3 5-6 From the above it seems that there is a definite time relationship between latent jaundice and the biliary colic

The presence of gall stones did not seem to have any material effect upon the latent jaundice In some patients who had a cholecystitis without stones, as for example Mrs J Case No 30, the icterus index of 12 indicated a hyperbilirubinemia, while in other cases (Mrs S B, Case No 101) the gall bladder was filled with stones and the index was but 5 5

At times following an attack of biliary colic the bilirubin content of the serum rose very markedly even though there was no evidence of jaundice elsewhere in the body After the attack subsided the serum bilirubin likewise diminished The following case will illustrate this

Mrs E W, age 42, was first seen on November 18, 1926 The family and previous history were negative The patient stated that she had been perfectly well until about two weeks before. The pain had no relation to food At 11 P M on November 17, 1926, the patient was suddenly seized with a very severe pain in the epigastrium She came to the clinic about 3 P M, and the icterus index, determined about one hour later, was 25 There was not the slightest evidence of apparent jaundice in spite of the high icterus index, which, when determined seven days later was 9 The patient was operated upon in March, 1927, and numerous biliary calculi were found in the gall bladder

In cases of uncomplicated Gastric and Duodenal Ulcer, the icterus index did not exceed 6 5 Bernheim[4] stated that cases of Gastric Ulcer gave a normal index and Duodenal Ulcer a higher icterus index In our group of patients there was no material difference in the icterus index of uncomplicated cases of Gastric and Duodenal Ulcer The indices varied from 4-6 5 The presence of latent jaundice in a case of Gastric and Duodenal Ulcer under observation always meant an associated affection of the biliary system The following was an example of this type that came to operation

R N, 46 years old, was first seen on January 13, 1926 He stated that eight years before he had had Typhoid Fever The past year he had been having a dull pain in the epigastrium and upper right quadrate soon after eating and lasting about two hours Food re-

lieved him at times Vomiting likewise relieved him The pain came on periodically, the patient being free from pains for weeks at a time The pain radiated to the right shoulder An analysis of gastric contents showed free Hydrochloric Acid = 40, Total Acidity = 80, blood negative The icterus was 10 5 An *x*-ray examination revealed the following Duodenal Ulcer with gastric retention, Cholecystitis

The patient was operated upon and the following was found "Chronic thickened ulcer one inch beyond the pylorus on the anterior superior portion of the duodenum The latter was attached to the gall bladder by old tough adhesions The gall bladder was enlarged and constricted at its middle The walls were thickened Diagnosis Ulcer of Duodenum and Chronic Cholecystitis Posterior Gastro-Enterostomy and Cholecystectomy were performed" The pathological report confirmed the diagnosis of Cholecystitis and Ulcer

The icterus index in the remaining group of our cases, which included Carcinoma of the Oesophagus and Stomach, Chronic Appendicitis, Post Operative Adhesions, etc, did not exceed 7, unless there was present an associated biliary affection Some of these patients came to the clinic with a history of very short duration and complained of symptoms that did not appear to be due to a gall tract affection Still, upon examination of the blood, latent jaundice was found to be present When the patient was operated upon, gall bladder disease was found in addition to the abdominal trouble which first appeared to account for all the symptoms

A case of this type was R H, age 18, first seen February 9, 1926 Family and previous history were negative The patient stated that for seven weeks he had been having sticking pains on both sides of the epigastrium below the costal margins, and especially over the lower right quadrate Fourteen days before, he had been taken ill with severe pains The pain radiated all over the right side They came immediately after eating but did not last longer than a few minutes Since the onset of the illness he had vomited once Physical examination revealed marked tenderness over the appendix The icterus index was 12 The gastric contents showed free Hydrochloric Acid=24, Total Acidity=56, blood negative The patient was operated upon on March 27, 1926 Chronic Cholecystitis and Appendicitis were found There was a broad band of adhesions extending from the gall bladder to the duodenum Cholecystectomy and Appendectomy were performed Pathological report confirmed the diagnosis of Chronic Appendicitis and Cholecystitis

Just as the presence of latent jaundice aids us in the diagnosis of abdominal affections, so at times the absence of latent jaundice will likewise help us In one of the cases of Carcinoma of the stomach, the icteric like appearance of the patient and the history pointed toward an affection of the liver The blood showed an icterus index of 3 5 This immediately ruled out any jaundice although the patient had an icteric hue At the operation an extensive inoperable carcinoma of the stomach was found The icteric appearance of the patient was due to the marked secondary anaemia

Comment—It can definitely be stated that latent jaundice is a valuable factor in abdominal diagnosis From the study of the above group of cases it appears that there is a relationship between the onset of pain and the ensuing latent jaundice But the number of cases that we could completely control were too few in number to make any extensive deductions This phase of the subject is still under study Whether calculi were present or not and the number did not have any material effect upon the latent jaundice A very important diagnostic point that was observed in the patients under study was that an icterus index indicating latent jaundice meant an affection of the biliary system The latent jaundice in abdominal affections may indicate disease of the biliary system, although a normal index does not necessarily exclude it

Conclusions

1 Latent jaundice is of inestimable value in abdominal diagnosis

2 Latent jaundice appears to have a time relationship to the onset of the biliary colic.

ALLERGIC DISEASES IN CHILDHOOD*

By T WOOD CLARKE, M D, UTICA, N Y

TWENTY-FIVE years ago, while making rounds in the Lakeside Hospital in Cleveland, Dr John Lowman asked a medical student the question "Why do we advise change of climate in a case of asthma?" The student replied "Because you can't do a thing for him, and hate to seem him hanging round your office"

At that time, if asked the chief cause of eczema, the average physician would have said the acid diathesis or acid in the blood When mention was made in 1906 to Sir Archibald Garrod, then Senior Physician to the Hospital for Sick Children in London, and now Osler's successor as Regeus Professor of Medicine at Oxford, of his father's brilliant piece of research work in associating excess of uric acid in the blood with gout, he said "Yes, it was a nice piece of work, but I wish he had never done it" On being asked why, he said "Because so many millions of people have been allowed to suffer from so many diseases because physicians have cloaked their ignorance, and satisfied their patients by explaining all sorts of ailments as being due to acid in the blood Gout is associated with excess uric acid No other disease is For every patient with gout that my father's discovery has relieved, a thousand sufferers from rheumatism, eczema, and what not have been improperly treated, due to the fallacy that these conditions are due to an acid condition of the blood" This was said by one who is not only one of the leading clinicians but also the outstanding medical chemist of England And yet our knowledge of the cause and correct treatment of eczema was so meager that "acid in the blood" was the almost universally accepted hook upon which to hang the cloak of our ignorance

Musser's Medical Diagnosis, edition of 1902, classifies hay fever as a reflex neurosis, and Osler's Practice of Medicine, passes over the causes of angio-neurotic oedema by saying that it is a hereditary disease

This briefly summarizes the extent of our knowledge in the first decade of the twentieth century of the diseases which are now grouped under the term "allergic diseases"

Following the introduction of serum therapy for diphtheria, it was found that whereas in the vast majority of cases antitoxin could be administered with impunity, occasionally sudden death followed its administration, especially in cases that had been given a previous dose of antitoxin The theory was developed that in some way the preliminary dose had made the patient hypersensitive to the serum This condition became known by the term anaphylaxis

The term "allergy" was first introduced by Von Pirquet to designate an artificial hypersensitiveness to tuberculin appearing during a course of tuberculin treatment The word as first used was synonymus with anaphylaxis Since that time there has been much confusion in the terminology of the various idiosyncratic conditions, but today it is generally agreed to apply the term anaphylaxis to the hypersensitiveness due to the artificial inoculation into the body of a foreign protein, while allergy is used to express a hypersensitiveness occurring accidentally or from natural causes

In 1912, Oscar M Schloss reported the case of a boy of eight years with a marked idiosyncrasy against eggs, oats, and almonds If any of these substances were ingested, immediate vomiting, intense swelling of the lips, tongue, and face, and profound collapse ensued In his study of this case, Schloss first called attention to the fact that if these substances were placed upon a small abrasion of the skin, an urticarial wheal appeared in a few minutes

Through the works of Goodale, Walker, Talbot, Moss, Coca, Cooke, and many others, this discovery of Schloss' has been elaborated, until today we have what is known as the skin test by means of which so much has been added to our knowledge of idiosyncrasies and the various diseases due to protein hypersensitiveness have become grouped under the name of the allergic diseases

The diseases at present considered as allergic in character are asthma, hay fever some types of bronchitis, eczema, urticaria, angioneurotic oedema, and certain acute gastro-intestinal upsets In the great majority of such conditions the true etiological factor may be determined with accuracy, and a rational line of therapy indicated by thorough investigation of each case by the use of the method of skin testing

The skin tests are made in various ways, and there is some difference of opinion as to which is the best method Schloss in his original experiments applied the powdered protein to an abrasion of the skin, made wth a Von Pirquet scarifier Talbot used an incision one eighth of an inch long made with a blunt knife, going through the superficial layer of the skin just deep enough not to draw blood He applied the powdered protein with a toothpick and dissolved it by applying decinormal sodium hydrate, also applied with a toothpick These are the two usual epidermal methods Cooke, on the other hand, uses protein in a liquid condition and makes his injection with a hypodermic needle endermically, as is done in the Schick test The endermic method is much more delicate than the epidermic and reactions can be obtained by this which will

*Read before the Oneida County Medical Society on January 8 1929, and before the Annual Meeting of the Medical Society of the State of New York, at Utica, N Y, on June 6 1929

not show at all when tested with the epidermic method The advocates of the epidermic method on the other hand, claim that the endermic method is too sensitive for practical purposes, positive reactions being obtained to substances to which the hyper-sensitiveness is so slight that they are not worth considering clinically Another objection is that where the endermic method is used on a patient with extreme hypersensitiveness, severe allergic shock may result which may even be fatal, while with the epidermic method there is very little danger of such an untortunate occurrence In my own work, I have used a combination of the methods of Schloss and Talbot, making my abrasion with a Von Pirquet scarifier and applying the decinormal alkali from a capillary tube such as is used in diluting diphtheria toxin in making the Schick test In small children the tests are made in line on each side of the spine, in older ones on the forearm With an amenable child about twenty tests can be applied in 15 minutes Twenty minutes later the materials are washed off with warm water and the results of the tests observed

The present paper is based upon an analysis of the records of 134 patients upon whom skin tests have been done during the last ten years In all, 135 different proteins have been used in these tests, and 3,723 individual tests made, 300 or 8 per cent of the tests being positive, 72 or 53 per cent of the patients have given positive reactions and 62 or 47 per cent negative The percentage of positive reactions would undoubtedly be higher were it not that in a number of the cases of infants, but a very few tests were made, and in a considerable number of other cases, after a few tests were made, the patients were not brought back for further study With the exception of one case of asthma and five of hay fever, examined at the request of other physicians, all the cases were children

The number of tests made with the various groups of proteins used and the comparative results are shown in Table I

The allergic diseases are so varied in their characteristics that it is difficult at first sight to see how they can be related, but there is abundant proof that they are all but different manifestations of the same underlying condition A characteristic history of an allergic child is something like this A baby, apparently normal while still nursing, develops a more or less severe degree of eczema This may improve when it is weaned and put on cow's milk At ten months of age the baby is given egg He promptly vomits it There may be an attack of urticaria or swelling of the lips or tongue Rarely the whole face and ears swell enormously Some weeks later, the child is again given egg, either the performance is repeated or the child refuses to take the egg The conscientious mother, feeling that egg is an essential element of the diet, conceals the egg or perhaps, after a considerable struggle and many punishments the child consents to take it Some weeks later, the child develops asthma, or recurring attacks of bronchitis The mother, with the best of intention has forced a serious disease upon her child, one which may take months or years to eradicate.

Total	3723	300	8

While various manifestations of the allergic conditions often occur on one patient, the infant with eczema becoming the child with asthma, or the baby with urticaria suffering from acute gastro-intestinal shock, for the sake of clarity the various manifestations will be discussed separately

The most commonly met manifestation of allergy is eczema This is the one concerning which there is the greatest difference of opinion, the pediatrists and the students of allergy believing that it is the important element in the disease, the dermatologists claiming that it is of but slight importance.

Of the seventy-seven cases of eczema reported today, 46 cases gave in all 153 positive tests, and 31 gave only negative tests, 60 per cent positive and 40 per cent negative An analysis of the 31 cases giving only negative tests shows that in 18 of these less than 10 tests were made, in only 4 cases were over 25 tests made and in only one over 50 If we eliminate from the record the 27 cases giving negative results in which less than 25 tests were made we find that we have 50 cases left, of which 46 or 92 per cent gave positive results From this it would be evident that if the investigation is made with even a moderate degree of thoroughness, it will be found that nearly 100 per cent of the eczema cases are shown to be allergic to one or more substances

A tabulation of the results of the tests in the eczema cases is shown in Table II

From Table II it will be seen that the classes of proteins which gave the largest proportion of

TOTAL	1,483	153	10		

positive results to the skin tests were egg with 44 per cent, animal hairs with 18 per cent, nuts with 15 per cent and silk with 14 per cent Milk and cereals were guilty in a few cases, while fruits, meats, fish, and feathers gave exceptionally few positive results A finding of particular interest is that in none of the 51 cases of eczema tested did the much maligned orange juice give a reaction In fact, in no case of any character have I been able to get a reaction to orange juice

The value of the exact knowledge of the substance or substances to which a child with eczema has an idiosyncrasy may be illustrated by the following three cases

Case I—W R W of Cassville Mother, aunt, grandfather and great grandfather had eczema At 3 months of age while still nursing, child developed severe eczema of the face When first seen at 5 months of age skin tests for egg white and yolk were made and found strongly positive The mother was told to eliminate egg from her diet and if the baby was not improved in two weeks, she was to come to the hospital for further tests The case was seen again at 10 months of age Elimination of egg had caused no improvement, but dread of hospital had made the mother visit various physicians and dermatologists in Utica instead of returning for the tests The eczema had continued unimproved On two occasions when cow's milk had been given, the child had been very croupy and remained so all night They thought it would suffocate The baby was sent to the hospital and positive skin reactions were obtained for egg white, egg yolk, cow's milk, human milk, wheat and oats negative tests were obtained for potato, soy bean barley, rye, bean and chicken A very small amount of cow's milk given by mouth caused marked swelling of the lips and urticaria of the face The child became wheezy

An attempt to wean the baby and feed it with soy bean and barley gruel was a failure as the baby refused to take the mixture, became listless and weak with irregular pulse and acetone in the urine The baby was again put to the breast and sent home with instructions to nurse for another month and gradually try to get it to take the gruel foods The mother was especially warned not to wean the baby until some safe artificial food was found

The day after its return, the mother gave it one feeding of malted milk The child became irritable, its face swelled to twice the normal size, the eyes disappeared, and the ears looked like elephant's ears The family physician ordered Justs food This seemed to agree for two days and he weaned the baby Two days later the baby vomited and developed a bloody diarrhœa, collapsed and became semicomatose The mother's breasts had dried up The baby was given soda and feedings of chicken soup, soy bean gruel and potato soup, as the skin tests had shown these to be safe foods for it It improved and brightened up markedly Two days later the local physician ordered the foods stopped The child again became semicomatose During these few days, though the child was in a critical condition, the eczema improved astonishingly

The child was brought to Utica and admitted to the hospital Further skin tests gave positive results for peanut, and negative for almond, beet carrot, cocoa, codfish, corn, walnut, lamb, mackeral, onion, orange, rice and spinach During its six weeks' stay in the hospital a diet was built up in accordance to the skin tests, egg, milk, oats and wheat being entirely eliminated The baby gained in strength and weight The eczema entirely disappeared and it was discharged in good condition Its sensitiveness to cow's milk was so great that the smallest amount of butter, even the trace found in butterine and oleomargarine would cause the eye lids to puff up so that the eyes would disappear This child was so allergic to so many foods considered essential in infant feeding that I believe any attempt to put it on an artificial food, without the help of the skin tests would have ended fatally Every slight variation from the path of safety as indicated by the skin tests caused alarming symptoms

Case II—A V , a child of a farmer in Camden, was referred by Dr Allison when 22 months of age in 1926 The family history showed asthma on both sides of the family The patient was a first child and had been nursed one year He had had three attacks of asthma Four months before his first visit he had begun to have eczema of face which had spread to arms and legs He felt ill and refused to go out-of-doors onto the farm The eczema was so complete that there was no normal skin on which to do skin tests The advice was given to continue the local treatment, to omit all eggs from the diet and to return as soon as enough normal skin was obtained for skin tests He returned a few weeks later with a small patch of skin on his back free from eczema A point which proved of interest later was that the mother had been lining his clothes with silk in order to keep the wool from the irritated skin

A series of 72 skin tests were made of which the following were positive Barley, bean, egg white, peach, peanut, radish, squash, tomato cat hair, cattle hair, horse dander and silk Wool was among the harmless substances whereas the silk gave an exceptionally strong reaction In the light of these findings, the father remembered that the eczema on the arms and legs grew much worse whenever the child went near the cows or was put on the horse's back

The offending foods were eliminated from the diet, silk was ordered removed from the clothing and therapeutic injection of horse dander and cattle hair were carried out by Dr Allison The eczema improved rapidly and in a few weeks had

went to boarding school the next year a well boy, and it is indeed a satisfaction to see him acting and singing in the performances of the Players Club, after seven years of freedom from the disease which cursed his entire childhood

Case V—J B, the son of a physician Seen first in 1925 when 3 years of age Father has asthma, hay fever and eczema The patient was nursed for 5 months and then put on cow's milk He developed eczema when 2 weeks of age and asthma at one year The asthma had been almost constant and was greatly aggrevated when he took an automobile ride in the country He was known to have an idiosyncrasy against eggs

Positive skin tests were obtained for egg white and yolk, codfish, peas and especially strongly for silk When this was brought out, it was stated that when riding he always sat in his mother's lap and that she always wore a silk coat

All silk was removed from the living room, the mother's silk gowns were put away and the father procured a mercerized linen tie The offending foods were forbidden In twenty-four hours the wheezing stopped and the child appeared quite well After a series of silk inoculations, the usual amount of silk was reintroduced into the room and clothing, and the child had no recurrence as a result

A few months ago, after being given egg, he developed a severe bronchitis with some asthma The child is not yet well as he has other idiosyncrasies, one being to glue, but it is hoped that further work along these lines will relieve him of these other allergies, as it did of that of silk Without the tests, it would have been difficult indeed to find the connection between a ride in the country and an idiosyncrasy against silk

The cure of asthma is usually a tedious process, but if all the patient's allergic idiosyncrasies can be discovered, there are few cases that cannot be completely cured If the patient is found to be sensitive to foods, they must be removed entirely from the dietary A child that is egg allergic, may have a violent attack of asthma simply from eating a baker's roll that has been glazed over the top with egg, or a piece of cake containing egg Clothing, which has proved to be offending must be removed If feathers are responsible, pillows and down quilts must be avoided If the hair of animals is the cause, they must be avoided, either as pets, in toys, or as furs Following a period of removal of the offending protein, the desensitization process must be begun, in the case of foods by feeding minute quantities of the protein and daily increasing the dose, in the case of hairs, feathers, and clothing by giving weekly hypodermic inoculations, starting with infinitesimal doses and gradually increasing This immunizing process usually takes from six months to a year, and as it is rarely wise to immunize against more than two substances at a time, it is sometimes necessary to give several courses in succession Thus the treatment may take several years to complete, but if it saves the child from the life of an asthmatic invalid, the time is as well spent as it is when the diabetic takes insulin or the syphilitic salvarsan

With hay fever my experience has been limited to 9 cases as this disease is much rarer in childhood than in the adult In fact, five of my nine cases were adults whom I tested either because they were personal friends of mine, or were referred to me by fellow practitioners who were not equipped with the test materials, and asked me to work the cases out for them All of these hay fever cases gave positive results to more than one pollen, four to two pollens, two to three pollens, and one each to five, seven and eleven pollens respectively A summary of these is shown in Table IV

TABLE IV

RESULTS IN 9 CASES OF HAY FEVER

	Number Tests	Number Positive	Per Cent Positive	Negative
POLLENS				
Plantain	2	2	100	Dock
Clover	3	1	33	Yellow Daisy

Giant Ragweed	8	4	50	
Short Ragweed	8	2	25	
Sunflower	8	2	25	
TOTAL	118	35	29	

There is much difference of opinion as to the value of pollen injections for hay fever I believe their value is in direct proportion to the care with which the preliminary skin tests are made, and the judgment used in the selection of the pollen to be used To proceed blindly with the inoculation of June grass in every early summer hay fever and ragweed in every late summer one, is but to invite disaster Where a comprehensive set of skin tests has been made, where the pollens to be injected are selected according to the vigor of the reaction and the botanical family to which the plant belongs, where the inoculations are given at sufficient intervals and started so far in advance of the hay fever season that the immunity has reached a high degree when the pollen blows, and these inoculations are kept up during the season very satisfactory results are obtained Unfortunately,

while in a certain proportion of cases one such series of inoculations produces a permanent cure, in many of them they have to be repeated in subsequent years The rapid daily inoculations begun at the beginning of the season, at times give relief, but are far inferior to those carried out slowly in advance

Closely related to asthma and hay fever are the cases of recurring coryza and bronchitis, which are the bane of every physician The more one studies the subject of allergy, the more one is led to believe that a considerable number of these cases are allergic in origin, and if adequately studied, the cause may be discovered and the attacks prevented One case will illustrate this aspect of the subject

Case VI—J L, now an Academy student has been under my care since he was three months of age At about the age of two years he began to have colds and attacks of acute bronchitis every few weeks His mother blamed the attacks upon his getting overheated, and said that she dreaded his going to his grandmother s home in the country because he always romped so hard and got so overheated while there, that he was sure to catch cold and have an attack of bronchitis Removal of his tonsils, cold baths in the morning, and every other means I knew were tried in my effort to prevent the colds, but with no avail When he was eight years of age, I suggested that I be allowed to try some skin tests, as they might give us a clue as to the cause of his repeated illnesses Twenty tests were made with the protein of foods, thirteen with pollens, and six with bacterins, all with negative results When I came to the hairs and feathers, however, the boy gave a strong reaction to cat hair His mother said it could not possibly be cats, as they lived in an apartment house and the boy never saw a cat He interrupted by saying, "Oh, mother, you know there are a lot of wild cats in grandmother's barn, and whenever I go there I have lots of fun catching them" He was instructed that in the future on his visits to his grandmother, he was to avoid the game of cat catching His attacks of bronchitis immediately stopped, and during the past eight years, he has been remarkably free of colds, though he romps, plays football and gets overheated in every way known to healthy youth

Time will not allow of a full discussion of the subjects of urticaria, giant urticaria, and angioneurotic oedema, but there is no question that many of these cases are allergic in origin, and that the underlying idiosyncrasies may be discovered and eradicated if they are studied from this point of view

Perhaps the most interesting and certainly the most worrying manifestations of allergy are the cases of acute gastro-intestinal shock, such as occurred in Case I described when discussing eczema, in which the child upon being given cow's milk vomited, had a bloody diarrhoea, and became unconscious In such cases, there is no time for any extensive series of skin tests, but a few tests can be made at once and if luck is with us, or if we have any clue as to the cause of the attack, startlingly brilliant results may be obtained Perhaps in such cases, even more important than finding what will cause an attack, is the discovery of what will not cause one As when a child is allergic to one food, he is usually allergic to several others also, the proper procedure in such cases is to remove all food for some hours, and gradually build up a diet containing no trace of any food except those for which negative skin tests have been obtained The process is slow and laborious, but in it alone lies safety A particularly interesting case has recently come under my observation

Case VII—J C M, thirteen months old, was sent to me a few weeks ago by Dr Girard of Lyons Falls The history obtained was that of a normal healthy child, which had been nursed for 9 months Four days before, the child was taken acutely ill with violent vomiting Everything taken by mouth had been expelled immediately The bowels had moved the first day, but not since except by enema There was no blood in the stools There had been no fever Dr Girard, suspecting some form of intestinal obstruction referred the baby to me Except for the lack of blood in the stools, the child suggested intussusception It was collapsed, quite limp, the eyes sunken, the temperature subnormal, the pulse weak and the abdomen relaxed Though no abdominal mass could be felt either by external or rectal examination, and there was no blood in the stools, it seemed safer to give the baby a barium enema and examine it under the fluoroscope This was done by Dr Powers immediately As the shadow of the sigmoid overlay the ascending colon, the examination was repeated later in the day We were convinced that there was no intussusception The baby, however, continued to vomit As the child was starving, that night one ounce of skimmed milk was given by mouth, every two hours The next morning the baby's face, arms, and legs showed a marked crop of urticaria. I then learned that they had never been able to give the baby cow's milk, except in small quantities and after boiling Skin tests were immediately made and positive reactions obtained for cow's milk, casein and lactalbumin and goat's milk Milk was discontinued, nutrient glucose enemata were given In a few hours the vomiting stopped and the baby, that had been so collapsed that it neither moved nor whimpered when the scarifier was applied to the back, soon began to show new life and when later tests were made, resisted vigorously In all tests were made with thirty-six food proteins, those of milk alone giving positive results A diet based upon the skin tests was built up, no food being allowed

until after a negative test therefor had been obtained The baby remained in the hospital one week gained a half pound in weight, and was sent home a healthy, vigorous infant, with a milk-free diet and instructions to return in two months, in order that the process of desensitization to milk could be undertaken

There is still one more situation in which I have found the skin tests to be of distinct value, and that is in regulating the diet of children who refuse to eat certain foods As the first symptom of an allergic idiosyncrasy is usually a dislike on the part of the child for the food which is a poison to him, I have found it well worth while in a number of children, with such distastes, to do skin tests for the foods they refuse to eat Herein lies the path of safety, for if the distaste is an expression of a true allergy and the food is forced upon the child, the results may be disastrous If, on the other hand, a skin test is made for every food concerning which there is controversy, one can tell the parents definitely whether or not the distaste is constitutional and must be respected, or is notional and should be suppressed

So far I have dwelt upon the bright side of this method of studying the diseases caused by individual idiosyncrasies I have shown that the etiology of a number of chronic conditions, previously considered mysterious, have been cleared up, and that a certain number of diseases, formerly considered more or less incurable, can be relieved I have shown that in other acute conditions of the gravest import the apparently impending fatality may be averted by a prompt study of the patient's allergic idiosyncrasies, and an intelligent application of the knowledge so obtained

Let me now say a few words on the dark side of the picture In the first place, we cannot promise results in all cases, but in what branch of medical science can we do so? The work is tiresome to physician and patient alike In an infant one can rarely do more than twelve tests at a sitting, and in an older child, the limit of his patience has been reached by the twenty-fifth test Though there is practically no real pain associated with the tests, young children are always frightened by the proceeding and struggle and scream during the entire time of the first investigation, and often at later sittings also, though an amenable child of four years, usually learns by the third time that the procedure has not the horrors he at first anticipated

If one gets one or more positive tests at the first sitting, the parents will usually have enough interest to return for later tests If the first tests are all negative, a certain proportion never return When definite results are obtained, enthusiasm is felt, but when a child is brought back eight or ten times and over a hundred tests are made all negative, it is difficult for both physician and parent to avoid discouragement

Fortunately, as more and more test materials become available, the proportion of unsuccessfully tested cases becomes less and less A recent step in advance has been that of making test solutions from the dust taken from the home of cases of asthma which fail to give reactions to the ordinary stock materials In a certain number of cases a reaction can be obtained from such dust, and there have been good results from therapeutic inoculations with extracts of such dust This is a delicate job, as the dust contains many different substances as animal hairs, sachet powders, feather dust and pollens, and as one has no idea which ingredient is the causative factor, one has no knowledge as to the strength of the dose being given However, when the usual methods fail, this should be considered Again when the stock material fails to give a test, for example to dog hair, a special test material made from the hair of a particular dog to which the patient is exposed, may solve the problem

Another drawback to the work is the fact, especially in cases of the allergic condition which have acute onsets as asthma, urticaria or gastro-intestinal crises that during the attack and for some days thereafter, the accuracy of the tests is greatly reduced It would appear that the explosion of the attack in some way renders the patient temporarily immune to the offending material, so that if a test is made during an attack of asthma or within a week following, a negative skin test may be obtained, with the very substance which has caused the attack Tests made at such time may be not only valueless but misleading

Human nature being what it is, most patients are willing to do anything to get relief at the time they are suffering, but forget all about the matter between attacks Great care must be taken to make the patients understand the necessity of returning during the well interval, if one is to keep their confidence in the face of a refusal to test during an attack

Whereas, when the epidermal method of testing is used, the procedure is quite safe and can be carried on in one's office, if the more delicate endermal method is attempted, the danger of shock is so great that it is doubtful whether it should be undertaken outside of a hospital, unless one has had extensive experience therewith

Perhaps the most serious drawback to this method of investigating the allergic diseases is the trouble and the expense In order to do the work adequately, one must keep constantly on hand at least one hundred and pref-

erably many more actively potent test proteins The active life of these proteins varies and outside of a research laboratory, there is no means of testing their potency For this reason they must be renewed at frequent intervals The materials are supplied in quantities of 25 to 50 mgm , enough for from five to ten tests only The stock has to be gone over every few days and those of which the supply is getting low, have to be renewed This takes time, trouble and money, sometimes to the extent of several hundred dollars a year For this reason, the method will never become popular in the hands of the general practitioner, who would probably see only a few cases a year and would not be able to devote the time or spend the money requisite for doing the work The only way that it can be done satisfactorily, is for a few men in each community to make a point of doing the work and for their confreres to refer their cases to them for investigation, and for recommendation as to treatment There are in most cities, some few men who are attempting to do this work more or less adequately, and I venture to say that very few of them are receiving a financial recompense in any way commensurate with the time or money being expended by them in keeping up their supplies Of course, the more referred work such men receive, the more thoroughly they can afford to do the work

In concluding allow me to say that this study of the diseases mentioned from the viewpoint of their allergic origin has passed the experimental stage, it has become an established branch of medical science The results obtained by this method of study are in a certain proportion of cases brilliant. There is no danger associated therewith Most of the conditions in question are by any other method of treatment, discouraging, and some are acknowledged to be incurable

In consideration of these facts, I believe that every case of asthma, hay fever, eczema, urticaria recurring bronchitis and allergic shock should be referred to some person equipped to do skin tests, to be studied from the viewpoint of their allergic origin I do not think I go too far when I say that a physician who treats these diseases without giving them the opportunity of having their allergic condition investigated, is practicing the medicine of the last century, and is no more giving his patient a square deal than is the man who treats acute appendicitis with olive oil instead of the knife, neglects to administer salvarsan in syphilis, and antitoxin in diphtheria, or allows a chronic gastric condition to go on for months without an x-ray examination

---

STRICTURE OF THE MALE URETHRA PROGNOSIS AS BASED UPON A STUDY OF 1244 CASES*

By MEREDITH F CAMPBELL, M D , NEW YORK, N Y

BECAUSE of the histo-anatomy of urethral stricture, the prognosis is reciprocal not only with the diligence, intelligence and persistence with which treatment by urethral dilatation is carried on but also with the incidence of local intercurrent infections While the clinical course of stricture is a highly individualistic phenomenon and the study of a comparatively few cases serves but to confuse and give false impressions, the observation of a large number of these patients with a careful scrutiny of their past records indicates that there is a certain prognostic uniformity which may be anticipated We have recently completed such a study in 1244 cases of stricture admitted to the Urological Service of Bellevue Hospital and from these observations have gleaned certain prognostic data in a relatively large cross section of stricture clinicopathology This data we are here presenting

Etiologically, urethral strictures may be grouped as (1) spasmodic or neurogenic, (2) congenital or (3) acquired Acquired strictures may be of traumatic origin or may follow inflammation and it is this group of lesions we are concerned with here Most traumatic strictures are found in the membranous urethra, they follow perineal "straddle injuries," and in this series comprised but 1 9% (23 cases) of the total number It is safe to state that 95% of all urethral strictures are due to gonorrheal infection, in but 60 of our cases was gonococcus infection denied and from some of these patients the organisms were isolated during hospitalization Although traumatic strictures are somewhat more dense form more rapidly and as a rule are more obstinately tenacious than inflammatory strictures for therapeutic and prognostic considerations we may regard them as clinically identical

Three-fourths of these patients were between the ages of 30 and 60 our youngest was 16 and our oldest 91 years of age (Table 1) The majority acquired their gonorrhea during their twenties, the period of greatest sexual activity and promiscuity, but in a surprisingly large number symptoms of stricture did not become manifest

* From the Urological Service of Bellevue Hospital

until after the age of forty (Table 2) We may state that in general slowly forming strictures will be more easily cured than those dense strictures of rapid origin, so often associated with an unusually virulent gonorrhea The earlier the stricture is exposed to therapeutic attack, particularly before advanced nephropathy has developed, by that much will the prognosis be rendered more favorable

TABLE II

Time relationship between Gonorrhea and initial Stricture symptoms

	Years							
	under 1	1	2	3	4	5 9	10 15	over 15
One attack only	27	92	43	32	35	29	133	299

Last G C		43	27	15	20	44	31	31

Of 714 having but one attack of gonorrhea, 15% developed clinical stricture within one year, five within two months The others had suffered one to a dozen attacks and a large number of these had been operated on previously for stricture, periurethral abscess or urinary extravasation (Table 3)

The pathological picture of stricture is that of scar plus inflammation with its associated local cellular infiltration involving the urethral glandular structures as well as the periurethral tissues Stricture is proportional to the intensity of the urethral infection rather than its duration and if several focal areas of intense inflammation develop along the canal, one may anticipate several strictures The intensity of the inflammation influences in no small degree the ultimate prognosis, small localized relatively superficial scars resulting from a rather mild infection will not be apt to give rise to serious clinical manifestations nor will great difficulty be encountered in dilating such lesions On the other hand, marked urethral and periurethral infiltration and scar will necessitate frequent and often life-long dilatation, the alternative being the prospect of an early death from urinary sepsis

Because of the inherent quality of scar tissue to contract, the pathological and, by the same token, the clinical picture of stricture is never stationary Clinical cure is accomplished not by removal of

the scar but by its overdilatation It must ever be borne in mind, however, that the acquisition of new urethral infections serve but to light up old stricture and a lesion apparently cured previously may again rapidly become tight and extremely dense By the consideration of such factors does the extreme difficulty of accurate prognosis regarding stricture become apparent A favorable prognosis therefore is rendered likely by absence of intercurrent infections (either newly acquired or exacerbative in character) and persistent treatment

The proper treatment of the gonorrhea is the best preventive treatment of stricture When the infection is well controlled or has subsided, the passage of steel sounds (24-28F) hastens the absorption of inflammatory exudate by acting as a gentle massage inciting temporary local congestion Most strictures do not require cutting, intelligent and persistent passage of sounds will cure most strictures and control all Scar is not removed except by excision but by the passage of sounds inflammatory infiltration will be absorbed A third of this series were not operated upon, a large number of those operated upon would not have been so treated except for economic reasons of greatest importance to these patients These individuals would not follow through the prolonged course of sounds required and in these cases a normal urethral calibre is most rapidly established by cutting In private practice, however, few strictures are encountered which will not respond to the passage of sounds over an extended period

Strictures of the meatus should be cut Firm stricture of the pendulous urethra often requires cutting but strictures of the bulb will usually yield satisfactorily to dilatation Strictures of the membranous urethra are usually traumatic in

origin and require urethrotomy Periurethral abscess and impassable stricture each demand incision Unfortunately, in the minds of many patients, urethrotomy promotes a false sense of security, they believe themselves permanently cured of their strictures and will not return for further instrumental dilatation As a prognostic factor, this point is of extreme importance and accounts in a great measure for the large number of patients we see whose lives have been checkered with urethrotomies If the passage of sounds of ample size (28-30F) is instituted within a week following urethrotomy and is continued regularly at five to seven-day intervals until the strictures no longer contract, the incised ends of the stricture band will not grow together but will heal widely separated If the instrumentation is not started at once, the firm sclerotic union of these cut stricture margins will bring about a scar of even greater intensity than existed preoperatively

That one should not delay post-operative instrumentation is suggested by the observation that of the 848 operative cases cut to permit the passage of a 30-32F sound to the bladder, 16 required reoperation because, when instrumented ten days after the first operation, the canal was found to be exceedingly tight or even impassable Obviously, in such cases, the original operation was of little value to the patient other than to establish temporary bladder drainage

Because of the prolonged urinary back pressure due to the urethral obstruction, renal function is greatly reduced Often gross destruction of the kidneys has occurred Renal infection is the rule with all except early cases of stricture Upon the remaining functional capacity depends in a great measure the hope of the patient for life and upon the preservation or augmentation of this function depends the prognosis Of the fatal cases of this series, the majority died of renal infection or renal failure. Two-hour phenolsulphonphthalein estimations were made in a third of the 1,244 patients and of this number, half excreted less than 30%, and three excreted no dye at all in two hours and four others but a trace Estimation of the blood non-protein-nitrogen (or urea) and creatinin indicates what the kidneys have been doing in recent days Of those cases in which such estimations were recorded, relatively few showed an extreme nitrogenous retention (Table 4) In general we may summarize by stating that the prognosis is unfavorable if the phenolsulphonphthalein excretion is below 20% in two hours or the non-protein-nitrogen is above 100 mgms or the creatinin above 4 mgms per 100 cc. of blood Many of these cases, however, will recover promptly

It is obviously impossible to follow such a large series of cases over a period of years especially since they have been cared for in a large city hospital and represent in no small measure a floating population We cannot therefore, base our prognostic data on the immediate results of our most recent treatment. We can however, by carefully studying the preoperative histories of these patients, estimate quite accurately what will be the ultimate result of our treatment and thereby determine the general prognostic index in a large series of patients suffering with stricture While realizing the unfairness of comparing such end results with those obtained in private practice among a more intelligent class of patient, it must be borne in mind that tissue reactions are in general alike We have observed stricture lesions in private patients (including three physicians (of nearly the same severity as in these charity hospital patients and should the former group deny themselves surgical attention to the extreme degree as the latter do, the ultimate clinical picture would be identical

TABLE IV

Functional Examinations

Phenolsulphonphthalein test (per cent in 2 hours intramuscularly)	
None	3
Trace	4
Under 5%	15
6-15%	88
16-30%	88
31-50%	131
Over 50%	101

Under 1 mgm 100 cc	6
1-2 mgms	201
2-3 mgms	69
3-4 mgms	12
Over 4 mgms	9
Non-Protein-Nitrogen	
Under 35 mgms 100 cc	317
36 to 50 mgms	122
51 to 75 mgms	36
75 to 150 mgms	11
Over 150 mgms	7

Of this series of 1,244 cases, 99 or 7 3% died Some (13) were not operated upon having been admitted to the hospital in coma and having died before urinary drainage could be instituted Exclusive of the extravasation cases secondary to stricture, the operative mortality was 4 9%, inclusive of urinary extravasation cases, 10 1% Over half (54 2%) of those stricture cases complicated by extravasation died Pneumonia was the immediate cause of death in eight patients, cardiac failure killed six, embolism one and paralytic ileus one Of the remainder most died of renal sepsis

Probably some of these stricture patients will be cured but the majority will continue an ir-

regular course of sounds during the lapses of which more scar will form and old scar will intensify This process will continue with the possible intercurrence of an acute urethritis Following this the patient may develop a periurethral abscess, urinary extravasation or suffer acute retention A severe prostatitis or even prostatic abscess may develop The patient may weather several such recurrences or the acute retentions may eventually become a chronic retention with overflow and an associated intercurrent acute renal infection is most likely to develop On the other hand, the only evidence of stricture may be dysuria, frequency and the presence of a gleet discharge with large shreds in the urine In any event, we find that within a period of a few years over a third of the entire number will require reoperation and of this relapsing group, a fourth will require reoperation within ten years Twenty of our patients had been operated on twice previously for stricture, seven three times, two four times, one seven and another nine times Three had had previous operations for extravasation, and twenty-nine had been operated on for periurethral abscess

In summary then, we may state that the prognosis of stricture is in direct ratio to the severity of the inflammatory scar and to the thoroughness of treatment The intelligent use of steel sounds will cure a few cases and control all Operative procedures are required in the presence of periurethral infection, impassable strictures or those which do not respond properly to sounds It should be forcibly impressed upon the mind of the post-urethrotomy patient that the operation is not the end but only a step in the progression to a cure Urethral dilatation must be started soon after operation and carried on until such time as the urethra will remain dilated It is important even then, that sounds be passed two or three times a year Of patients in whom this schedule is not followed, a third will require reoperation, a fourth of this number will require reoperation within ten years In considering the prognosis in a given case, the renal function and presence or absence of renal complications always merit most serious consideration since renal function is the thread by which the life of the patient hangs

---

SOME PRESENT TRENDS IN THE TREATMENT OF PEPTIC ULCER*

By HOWARD F SHATTUCK, M D, NEW YORK, N Y

THE persistent effort to arrive at a uniform procedure in the treatment of peptic ulcer in the past few years has borne fruit in spite of the uncertainty and conflicting data on the subject Unfortunately the ideal treatment medical or surgical, is not yet in sight Yet there can be no question that accumulating experience and the studies of large groups of ulcer-bearing patients have considerably improved ulcer treatment in recent years A vast literature on ulcer continues to appear, making it rather difficult for anyone not especially interested in the subject to follow the present trends in its treatment It is the purpose of this paper to point out briefly just what seem to be the most generally accepted changes that have occurred recently in ulcer management

There has been a distinct swing of the pendulum toward medical management before resorting to surgery, except with complications and certain types of ulcer Many of our most able and experienced surgeons have taken a leading part in this change of attitude Let me quote three of them Lahey[1] states that it is his policy to operate in peptic ulcer

1st—In cases of perforated ulcer

2nd—In unrelieveable obstruction

3rd—In cases of recurrent hemorrhage

4th—In all cases where there is a reasonable ground for suspicion of carcinoma

5th—In cases of failure with medical management

He further states that obstruction due to ulcer medically unrelievable is a rarety in his experience, and that the group in which surgery has been done in his clinic for failures with medical management is a small one Certainly Lahey seems like an ultra-conservative regarding surgery in peptic ulcer compared with many internists Sir Berkeley Moynihan[2] holds that "It is at least arguable that the necessity for surgical relief in many cases is due to a too perfunctory trial of medical treatment" He advises before resorting to surgery that "a really serious attempt to treat all cases of chronic peptic ulcer by medical treatment should be made" William J Mayo[3] states "each case must be considered individually, and when it is reasonably possible, careful medical management of the ulcer should be given a thorough trial before operation is recommended" Thus it appears that indiscriminate surgery for peptic ulcer before a trial with medical treatment, is as bad practice as to withhold operation for cases of repeated hemorrhage and organic pyloric obstruction

At the same time there is an unmistakable trend to more and more radical surgery in dealing with peptic ulcer First, we had gastro-enterostomy,

*Read before the Clinical Research Society, New York City April 30, 1928

then pyloroplasty, succeeded by various forms of pylorectomy and excision, and lastly by subtotal gastrectomy with complete exclusion of the ulcer-bearing area Of course these extremely radical surgical procedures are by no means universally accepted by the surgeons themselves, while they are causing no little uneasiness among the internists

In the medical management of peptic ulcer, definite changes have taken place in the last few years There are still several different plans of management all strongly supported by their advocates and all yielding apparently equally good results in the hands of those skilled and experienced in their use

Frequent Feedings Duodenal feeding with one of the duodenal tubes gives considerable digestive rest and was widely used during the war period It is disagreeable for most patients however, and has been generally abandoned, except by a very few The principle of frequent feeding of a bland fluid and soft diet seems to be the most important part of the medical treatment and is common to all forms now in general use Sippy's orthodox treatment calls for hourly feedings long continued, but in recent years two hourly feedings have been very frequently used As the treatment progresses the periods have even been lengthened to every three hours by some In addition, there is an increasing tendency now to continue these frequent or intermediate feedings, usually of milk, for two years or longer, as I will point out later in connection with the duration of treatment

Alkalis There has been a distinct change regarding the use of alkalis Until a few years ago it was quite general to follow the lead of Sippy by using large amounts of alkali every hour for a very long period When it was found, however, that these massive doses produced alkalosis and other toxic effects in some patients, and that most patients did very well with greatly reduced amounts of alkali, or none at all, their use was considerably modified or abandoned While some modification of Sippy's treatment is still more widely used than any other, few men follow him in attempting to completely neutralize the free hydrochloric acid with alkalis Some do not use them at all as a routine, but the majority still continue the use of alkalis in small amounts at the beginning of treatment at least to help to bring the distress symptoms under rapid control

Duration of Treatment The follow-up studies of large groups of ulcer-bearing patients that have been carried out in the last ten or fifteen years have profoundly modified our attitude regarding the length of time that medical treatment should be carried out Many patients even now are carefully treated for only a few weeks or months Alvarez,[4] at the Mayo Clinic, recently on questioning 100 patients who had been previously treated medically for ulcer, found that "most of them had been allowed to return to a full diet within a few days or weeks after a cure" Many have recurrences because they return too soon to an unrestricted diet, the use of alcohol, tobacco, etc Recently I have seen three young patients, symptom free for over a year and showing favorable X-ray improvement, who have had relapses following the use of alcohol and the failure to keep up some intermediate feedings Some patients may get a so-called medical cure in one year But, it is best for all to follow a restricted diet, abstain from alcohol and have intermediate feeding for two years at least. Some patients will have to follow a somewhat restricted diet much longer, perhaps for the rest of their lives The success of the physician in getting a satisfactory medical result will depend, in a very large number of cases, on his ability to persuade his patients to carry out medical treatment for a sufficiently long time It need not be as careful a treatment as that used in the first few weeks, but it does need to be restrictive treatment just the same

All patients with ulcer should be firmly and repeatedly impressed with the necessity of long patient, faithful observance of the rules They must be taught to take care of their ulcers just as patients are taught to take care of their diabetes or tuberculosis All this takes time and infinite pains It is this part of the treatment that is more often neglected than any other And this neglect is undoubtedly the most frequent cause of failure with medical treatment

Until some better method of treating ulcer is found some patients will have to be careful about their diet and habits for the rest of their lives This applies equally well to many patients following operation for ulcer The rather disappointing late results of medical treatment with ward patients from the lower economic classes of our population, is due in a large measure to their inability or unwillingness to continue the treatment under medical supervision during the months following their discharge from the hospital Consequently we must expect a much larger number of these patients to come to surgery and at an earlier period than private patients do It is largely a problem of economics and intelligence

Exercise It has been pointed out that there is often an unfavorable effect on duodenal ulcer from tugging on the duodenum resulting from certain movements in bending and lifting It is not an uncommon experience for patients to have a recurrence of symptoms following hard work or strenuous exercise For this reason it is much more general now to forbid hard physical work or strenuous exercise during the active treatment of ulcer Walking is about all that is permitted in the beginning Of course patients become restive under these restrictions and often rather take

regular course of sounds during the lapses of which more scar will form and old scar will intensify. This process will continue with the possible intercurrence of an acute urethritis. Following this the patient may develop a periurethral abscess, urinary extravasation or suffer acute retention. A severe prostatitis or even prostatic abscess may develop. The patient may weather several such recurrences or the acute retentions may eventually become a chronic retention with overflow and an associated intercurrent acute renal infection is most likely to develop. On the other hand, the only evidence of stricture may be dysuria, frequency and the presence of a gleet discharge with large shreds in the urine. In any event, we find that within a period of a few years over a third of the entire number will require reoperation and of this relapsing group, a fourth will require reoperation within ten years. Twenty of our patients had been operated on twice previously for stricture, seven three times, two four times, one seven and another nine times. Three had had previous operations for extravasation, and twenty-nine had been operated on for periurethral abscess.

In summary then, we may state that the prognosis of stricture is in direct ratio to the severity of the inflammatory scar and to the thoroughness of treatment. The intelligent use of steel sounds will cure a few cases and control all. Operative procedures are required in the presence of periurethral infection, impassable strictures or those which do not respond properly to sounds. It should be forcibly impressed upon the mind of the post-urethrotomy patient that the operation is not the end but only a step in the progression to a cure. Urethral dilatation must be started soon after operation and carried on until such time as the urethra will remain dilated. It is important even then, that sounds be passed two or three times a year. Of patients in whom this schedule is not followed, a third will require reoperation, a fourth of this number will require reoperation within ten years. In considering the prognosis in a given case, the renal function and presence or absence of renal complications always merit most serious consideration since renal function is the thread by which the life of the patient hangs.

SOME PRESENT TRENDS IN THE TREATMENT OF PEPTIC ULCER*

By HOWARD F. SHATTUCK, M.D., NEW YORK, N. Y.

THE persistent effort to arrive at a uniform procedure in the treatment of peptic ulcer in the past few years has borne fruit in spite of the uncertainty and conflicting data on the subject. Unfortunately the ideal treatment medical or surgical, is not yet in sight. Yet there can be no question that accumulating experience and the studies of large groups of ulcer-bearing patients have considerably improved ulcer treatment in recent years. A vast literature on ulcer continues to appear, making it rather difficult for anyone not especially interested in the subject to follow the present trends in its treatment. It is the purpose of this paper to point out briefly just what seem to be the most generally accepted changes that have occurred recently in ulcer management.

There has been a distinct swing of the pendulum toward medical management before resorting to surgery, except with complications and certain types of ulcer. Many of our most able and experienced surgeons have taken a leading part in this change of attitude. Let me quote three of them. Lahey[1] states that it is his policy to operate in peptic ulcer:

1st—In cases of perforated ulcer.

2nd—In unrelieveable obstruction.

3rd—In cases of recurrent hemorrhage.

4th—In all cases where there is a reasonable ground for suspicion of carcinoma.

5th—In cases of failure with medical management.

He further states that obstruction due to ulcer medically unrelievable is a rarety in his experience, and that the group in which surgery has been done in his clinic for failures with medical management is a small one. Certainly Lahey seems like an ultra-conservative regarding surgery in peptic ulcer compared with many internists. Sir Berkeley Moynihan[2] holds that "It is at least arguable that the necessity for surgical relief in many cases is due to a too perfunctory trial of medical treatment." He advises before resorting to surgery that "a really serious attempt to treat all cases of chronic peptic ulcer by medical treatment should be made." William J. Mayo[3] states "each case must be considered individually, and when it is reasonably possible, careful medical management of the ulcer should be given a thorough trial before operation is recommended." Thus it appears that indiscriminate surgery for peptic ulcer before a trial with medical treatment, is as bad practice as to withhold operation for cases of repeated hemorrhage and organic pyloric obstruction.

At the same time there is an unmistakable trend to more and more radical surgery in dealing with peptic ulcer. First, we had gastro-enterostomy,

*Read before the Clinical Research Society, New York City, April 30, 1928.

then pyloroplasty, succeeded by various forms of pylorectomy and excision, and lastly by subtotal gastrectomy with complete exclusion of the ulcer-bearing area Of course these extremely radical surgical procedures are by no means universally accepted by the surgeons themselves, while they are causing no little uneasiness among the internists

In the medical management of peptic ulcer, definite changes have taken place in the last few years There are still several different plans of management all strongly supported by their advocates and all yielding apparently equally good results in the hands of those skilled and experienced in their use

Frequent Feedings Duodenal feeding with one of the duodenal tubes gives considerable digestive rest and was widely used during the war period It is disagreeable for most patients however, and has been generally abandoned, except by a very few The principle of frequent feeding of a bland fluid and soft diet seems to be the most important part of the medical treatment and is common to all forms now in general use Sippy's orthodox treatment calls for hourly feedings long continued, but in recent years two hourly feedings have been very frequently used As the treatment progresses the periods have even been lengthened to every three hours by some In addition, there is an increasing tendency now to continue these frequent or intermediate feedings, usually of milk, for two years or longer, as I will point out later in connection with the duration of treatment

Alkalis There has been a distinct change regarding the use of alkalis Until a few years ago it was quite general to follow the lead of Sippy by using large amounts of alkali every hour for a very long period When it was found, however, that these massive doses produced alkalosis and other toxic effects in some patients, and that most patients did very well with greatly reduced amounts of alkali, or none at all, their use was considerably modified or abandoned While some modification of Sippy's treatment is still more widely used than any other, few men follow him in attempting to completely neutralize the free hydrochloric acid with alkalis Some do not use them at all as a routine, but the majority still continue the use of alkalis in small amounts at the beginning of treatment at least to help to bring the distress symptoms under rapid control

Duration of Treatment The follow-up studies of large groups of ulcer-bearing patients that have been carried out in the last ten or fifteen years, have profoundly modified our attitude regarding the length of time that medical treatment should be carried out Many patients even now are carefully treated for only a few weeks or months Alvarez,[4] at the Mayo Clinic, recently on questioning 100 patients who had been previously treated medically for ulcer, found that "most of them had been allowed to return to a full diet within a few days or weeks after a cure" Many have recurrences because they return too soon to an unrestricted diet, the use of alcohol, tobacco, etc Recently I have seen three young patients, symptom free for over a year and showing favorable X-ray improvement, who have had relapses following the use of alcohol and the failure to keep up some intermediate feedings Some patients may get a so-called medical cure in one year But, it is best for all to follow a restricted diet, abstain from alcohol and have intermediate feeding for two years at least Some patients will have to follow a somewhat restricted diet much longer, perhaps for the rest of their lives The success of the physician in getting a satisfactory medical result will depend, in a very large number of cases, on his ability to persuade his patients to carry out medical treatment for a sufficiently long time It need not be as careful a treatment as that used in the first few weeks, but it does need to be restrictive treatment just the same

All patients with ulcer should be firmly and repeatedly impressed with the necessity of long patient, faithful observance of the rules They must be taught to take care of their ulcers just as patients are taught to take care of their diabetes or tuberculosis All this takes time and infinite pains It is this part of the treatment that is more often neglected than any other And this neglect is undoubtedly the most frequent cause of failure with medical treatment

Until some better method of treating ulcer is found some patients will have to be careful about their diet and habits for the rest of their lives This applies equally well to many patients following operation for ulcer The rather disappointing late results of medical treatment with ward patients from the lower economic classes of our population, is due in a large measure to their inability or unwillingness to continue the treatment under medical supervision during the months following their discharge from the hospital Consequently we must expect a much larger number of these patients to come to surgery and at an earlier period than private patients do It is largely a problem of economics and intelligence

Exercise It has been pointed out that there is often an unfavorable effect on duodenal ulcer from tugging on the duodenum resulting from certain movements in bending and lifting It is not an uncommon experience for patients to have a recurrence of symptoms following hard work or strenuous exercise For this reason it is much more general now to forbid hard physical work or strenuous exercise during the active treatment of ulcer Walking is about all that is permitted in the beginning Of course patients become restive under these restrictions and often rather take

their chances with vigorous exercise or change to some physician who is less strict Some get sick and tired of medical treatment and resort to surgery without further delay

Ambulatory Treatment Most of the standardized forms of medical treatment of ulcer include a preliminary rest period as an important part of the regime And it has been generally believed that mental and physical rest play a large part in the success of medical treatment It was one of the cardinal principles of Sippy However, the large number of patients unable to afford the time and expense of the preliminary rest treatment has resulted in the use of ambulatory treatment with an increasing number of these portions of our population in the lower economic strata In a recent questionnaire among the members of the American Gastro-Enterological Association, Carter[5] discovered that a considerable number favored the ambulatory type of treatment No mention was made as to whether these men used it exclusively or only when conditions required it But he further found that satisfactory results reported with ambulatory treatment were distinctly lower than with the preliminary rest treatment, being 32 per cent as against 61 per cent Alvarez[4] has presented the case of ambulatory treatment more strongly perhaps than any other Despite this unmistakable trend toward a wider use of the ambulatory form of treatment, my personal conviction is that where preliminary rest is reasonably possible, better results will follow in the long run when it is used It removes mental and physical strain And like the preliminary hospital treatment of a patient with diabetes, it provides a splendid opportunity to train the patient in the care of his disease under strict control

It must be remembered that peptic ulcer is a fairly common condition Most of the patients will be cared for by the average general practitioner under average conditions Accordingly, we must have a simple, workable plan of treatment that can be applied by the average physician to the average patient Such a plan is the ambulatory regime of frequent feedings, say every two hours, with three meals of suitable soft, bland food with or without the administration of small amounts of alkalis three or six times a day Still better forms of treatment will be available for those who can afford the time and extra expense connected with them But we must be prepared as in so many other chronic diseases to adjust the treatment to the patient's economic and social status when necessary

There are a number of other considerations, such as the use of tobacco and the removal of foci of infection that might be considered We can merely allude to them here There is still a little diversity of opinion about the use of tobacco, but I think that most careful observers favor stopping it altogether, at least for a long period during active treatment The status regarding foci of infection is essentially the same as in other conditions associated with them, with perhaps a swing of the pendulum away from the extreme radicalism of a few years ago Of the constitutional tendency to ulcer or ulcer diathesis, so called, we know very little But present studies on human constitution such as those being made by Draper, are sure to shed light on this exceedingly interesting and perplexing problem

In conclusion it may be said that some of the recent trends in the treatment of peptic ulcer are as follows

1 It is quite generally accepted that, excluding complications and certain types of ulcer, all peptic ulcers should first be given the benefit of suitable medical treatment before resorting to surgery

2 The principle of frequent feedings long continued is recognized as the most important part of medical treatment

3 No general agreement exists about the role of alkalis in medical treatment The prolonged use of excessive amounts, as advocated by Sippy has been largely abandoned And while some methods of treatment do not include alkalis at all, most of them use small amounts of alkali in the beginning, at least, to bring the distress symptoms under rapid control

4 The duration of medical treatment has been extended from a few weeks or months to at least one or two years, possibly longer It is now recognized that some patients have to follow certain restrictions for the rest of their lives

5 More attention has been paid in recent years to restricting certain forms of physical activity during the early months of medical treatment

6 The great majority of those especially interested in ulcer treatment, still favor the preliminary rest treatment when it is possible But the large number of ulcer patients who cannot afford the time and expense for such treatment has brought about a much greater use of the ambulatory type of treatment for these patients

7 Tobacco and alcohol are now generally prohibited for long periods

8 Obvious foci of infection are eradicated at the start, but the pendulum, has swung away from the ultra radicalism of a few years ago regarding foci

THE HEALTH EXAMINATION—SOME FUNDAMENTAL CONSIDERATIONS*

By C WARD CRAMPTON, M D, NEW YORK, N Y
From the Committee on Health Examinations Medical Society of the State of New York

The study of the status of the health examination in medicine, economics, and every-day affairs reveals a diversity of faith and practice An assay of the situation may aid discussion, work toward agreement, and facilitate progress The health examination is a new and rapidly developing subject It needs landmarks The following discussion is prompted by this need

Definition—1 A good definition should recognize the three essentials of the examination (1) the health client, (2) the purpose of the examination, (3) and the examiner

2 'The medical examination of a man in good health" may serve the purpose of a brief definition The following is more exact and descriptive "A health examination is an inspection of a man (presumably in health) to defeat disease and deterioration, increase health, happiness, and efficiency by every way possible to a skilled, understanding medical adviser"

We must also define our new terms as we adopt them The term "health client,' referring to the health examinee, and 'preclinical signs," recommended four years ago, seem to be increasingly approved (*Medical Journal and Record*, Oct 21, 1925, "The Health Examination and Its Distinctive Features" by C Ward Crampton, M D) The health examination, however, can only be adequately defined by describing it It has for its initial purpose the discovery of disease conditions actively present This is all that the health examination means to most physicians and the general public This is reason why the average man is afraid of the health examination It connotes something destructive This has been the chief obstacle to its progress

The second function of the health examination is to discover the preclinical signs of oncoming disease The term 'preclinical' is new It refers literally to the stage previous to taking to one's bed (cline = bed) Preclinical signs of disease may be found (1) In the anatomical structure of the client (2) By physiological tests, (3) The observation of certain deviations from the normal, (4) The study of life habits, (5) Conditions, (6) Environment, (7) The record of previous illnesses (8) The study of the lives of ancestors and collaterals The health examination has to do with disease present in the first case and potential, preclinical) in the second This is the pathological aspect of the health examination

It has another aspect which relates to conditions which are the opposite of disease, to wit, health, happiness, vigor, efficiency, and long life In a sense, all these desirable positive human states are made possible only by the absence, or relative absence, of disease The best way to work toward long life is to remove those things which shorten life These are largely pathological Similarly the most efficient way to preserve youth, increase vigor, and happiness is to remove those pathological conditions which destroy them In addition to these anti-pathological efforts, there is, therefore, a constructive phase of the health examination which seeks by the regulation of life and various physiological, psychological, and social means to increase the abundance of the fruits of health and make the living of life more keenly desirable and worth while living long

This difference in point of view is illustrated by the following story which is told about a patient in a celebrated sanitarium He had been examined by many doctors in many ways and by many impressive processes over a period of a week Thoroughly exhausted, he was given his final interview by the head physician, who stated as follows "You are a very sick man Thus and so is much impaired, and this and that are quite seriously damaged, but, if you follow our advice, keep under our care, eat no meat, stop smoking, never take a drink, and go to bed at nine o'clock every night, you will live perhaps ten years longer" The patient fixed his consultant with a dim and baleful eye and replied "What for?"

Thus there are three departments of medicine recognized in the health examination (1) the pathological, (2) the preclinical, and (3) the constructive (positive health) To define completely the health examination requires a far more extensive and incisive analysis For this purpose the following headings are suggested

1 Purpose
2 Content
3 The health client (different kinds)
4 Time consumed in the health examination
5 Place and circumstance (office, clinic, home, contest, campaign)
6 The examiner and his status (private practice employed, group, hospital)
7 The economics, cost, worth, and value

A brief reference to each topic is important Each division interlocks with every other and the discussion of one touches upon all

Purpose—There are quite a variety of purposes in mind when a presumably healthy person is examined by a physician

1 The health examination may have a very limited purpose Persons handling food must be

*Much of an address on The Economic Aspects of the Health Examination" delivered before the Medical Alliance on May 2 1929 has been employed in this article.

examined to make sure that they are not suffering from any contagious disease and the Wassermann test is considered the chief essential The purpose is primarily protection of others Technically this is a health examination because the examinee is presumably in good health It is sufficient for its very limited purpose and we must value it accordingly

2 The insurance examination has for its purpose the protection of the company against bad risks It seeks to find out if the examinee will die too soon thereby costing the company more money than he has paid in premiums This examination is technically a health examination because the examinee is presumably in health It fulfills its purpose as well as may be We must not expect it to benefit the examinee That is not the intention It may help make him aware of his status and thereby function as a good health examination As a rule, however, if he passes it, he gets a false sense of security and this provides an excuse for omitting a real health examination This does harm

The health examination offered by insurance companies to their policy holders is different This purpose is to prolong life so that more premiums may be paid into the treasury of the company This is a real health examination in so far as its purpose is concerned, however limited it may be in its scope and merit It does good It must be valued accordingly

3 The usual health examination is confined exclusively to pathology in its simplest and most evident form The question is asked by the health client, "Have I any disease I do not know about?" The doctor thereupon looks for disease He finds it or he does not find it He gives an answer, "You have no disease You are all right Come in next year"—or, "You have such and such a disease You must do so and so" This search for disease is, in the opinion of many, a complete health examination Such, however, is not the case Nevertheless it does much good The world would be a better place if people generally had these examinations and the physicians generally gave them This examination may be as much as we legitimately can ask of the public and of the physician in general for the next decade It may be politic for us to make this examination the standard and work for this alone until we can go further The examination, however, neglects two fields The first is the *Preclinical* field This answers the question, "Are there any signs of oncoming illness against which I can take reasonable measures," and the second, the *Positive Health* field which inquires, "Are there any ways in which I might be made more vigorous, happy, and efficient?"

The field of pathology is familiar to the physician It is extensive and vital to public welfare The preclinical field is new to the physician It is promising, vastly more extensive than the field of pathology and equally important though not so urgent The positive health field of constructive medicine with its concern with the higher degrees of vitality and happiness is a definite luxury In this field the physician has hardly entered The charlatan has preceded him

The foregoing serves to illustrate some of the various purposes of the health examination

Content

A *Pathology*

Strangely the one element upon which all students of the health examination agree is the search for disease This search should be thorough Every region of the body must be gone over with care The old-fashioned doctor theoretically knew the whole body Recently the body has been cut up into various regions or systems in which the appropriate specialist rules with authority Recognizing this, we must go to the specialist for regional information, and, we hope, simple diagnostic methods The first effort in this direction was that of the New York County Medical Society which published the addresses of a series of specialists in the New York Medical Journal and later as a separate volume in 1925, printed and circulated by the New York Tuberculosis Association This has been followed by a book by Fisk and Crawford "How to Make a Periodic Health Examination" (New York, Macmillan, 1927) and recently by a volume "Preventive Medicine" by the Public Relations Committee of the New York Academy of Medicine (New York, Hoeber, 1929) All these publications deal with regional pathology but very little with preclinical medicine and almost nothing with positive health Most of the health examination forms, including those of the American Medical Association, are primarily records of pathology though there is evidenced everywhere a desire to enter the field of preclinical and constructive medicine

Much work still needs to be done in the organization of the field of simple, evident pathology and its adaptation to the needs of the health examination It will always be the most important part of the health examination for it deals with the urgent, vital, dangerous, and immediate It will never be the whole of the health examination

B *Preclinical Signs*

Preclinical signs of disease are those which appear before the man must take to his bed, as we have explained We must divide them into two groups The first group of preclinical signs is clearly pathological and comes in the category above discussed The second group contains signs which, though not in themselves pathological, indicate various degrees of probability of future ill-

ness In the first group, the pathological preclinical signs, many are familiar, viz, the appearance of albumin or sugar in the urine, a lump in the breast, a diseased tonsil, a positive Wassermann reaction, high blood pressure, and the like All of these and hundreds of other pathological signs appear preclinically, i e, before the man is sick enough to go to bed This is the great and undisputable field of the health examination It needs the vigorous services of clear sighted physicians in every specialty in medicine

The second group of preclinical signs contains many clear indications that a disease is approaching, or that it is likely to occur, or that it is more likely to occur in this kind of person than in the average person These signs are less clear, less certain and difficult to isolate Some are definite, others verge upon the speculative They are understood best by the biometrician, on the one hand, and the old-fashioned family doctor who saw people go through a life time On the other hand, they are least understood by the practical every day doctor who deals only with people already sick or seriously damaged, who seldom has time to raise his head from the distress or illness and wonder what were the beginnings of all this trouble and destruction This is the field in which preventive medicine will advance in the next five decades In this field the explanation and solution of myocarditis, nephritis, diabetes, and possibly cancer will largely be found Chronic diseases, as we see them at the death bed, are merely the terminal phenomena of a series of changes and adaptations which have progressed through several stages, the last of which we, in our restricted pathological field, are permitted to see The first six or seven stages of stenocardia may be in the preclinical field, and they may be quite remote from the heart We have a long way to go in this field before we can rightfully claim to be following the old adjuration *Obsta principiis* (Resist the first beginnings) This is the unique field of the health examination and it is a great opportunity for scientific service

Preclinical signs may be found in heredity and the study of collateral relatives, in the habits and environment of life, in the study of past illnesses, in the anatomical structure of the body, and in the physiological tests Each one of these topics requires extended and detailed consideration not possible in the present discussion

The third variety of medical effort found in the complete health examination is Constructive Medicine This recognizes the fact that ordinary average health is a thing of mediocrity It is not more desirable and satisfactory than the ordinary average income Average ordinary health implies a state far below the optimum and, in most cases, far inferior to what may be hoped for, expected, and realized This is the field of hygiene, life regulation, reasonable exercise, rational diet, and sensible life management This is primarily a medical field The doctors neglect it because they feel it is beneath them It lacks the tang of emergency, the drama of rescue They should prescribe and regulate the health producing elements of living They may be aided by ethical practitioners in exercise, massage, and the like This field should not be left unregulated for the cultist to develop The medical profession can do much to increase their service in the field of positive health

Thus the health examination consists broadly of three interlocking departments of medical effort

1 Pathology—its recognition and amelioration

2 Preclinical signs—their recognition and the institution of reasonable precautionary measures

3 The effort toward optimum health, Constructive Medicine

The Health Client

The next variable in the health examination is the health client himself There are two kinds of health clients The first come to the examination because they wish to get its benefits The second class, however, are sent for the examination by an employer, or they are required to take it in order to gain some privilege The first is voluntary, the second is obligatory The second class, who received the impetus toward the health examination from necessity, outnumber six to one those who come to the examination of their own accord This is an important consideration in the study of the subject.

The voluntary health client is assumed to be in good health Such is not always the case In fact most of the men who come to the doctor's office for a health examination suspect they are not well and have reasons for their suspicions There is, of course, a small proportion of men who have studied the health examination question, decided that it was good, and proceed to get the prospective benefits They are counseled by wisdom They are very few

The second class are the apprehensive They are by far the most numerous They are afraid of some unknown, oncoming illness because of some discomfort or minor disability and come for examination to be relieved of their fears

The third class who come for the health examination are those who are counseled by despair They have one or more chronic illnesses They have sought relief from one physician after another and have not obtained it They have hope of the health examination which goes thoroughly through every part of the body, so different from some of the examinations they have had They cherish a gleam of hope that by this process they will solve an apparently hopeless problem And, sometimes they are right Thus there are three classes of health examinees, the confident, the ap-

prehensive, and the despairing, prompted respectively by wisdom, fear, and hope

The obligatory health examination is found principally in industry The employer requires an examination and certification before employment As a rule, the examination is general and thorough enough only to meet the needs of the employer Its standards rise and fall with the labor market It always emphasizes some particular element related to the trade in question The huge number of these examinations, the fact that they are done by organizations in a wholesale manner, makes this branch of the subject of peculiar importance from the standpoint of medical economics As a rule, this kind of examination results in approval or disapproval It does not, as a rule, give any information to the client and he receives little or no benefit therefrom In this respect much advance may be made

Similar examinations are made by Labor Unions before admission The huge bulk of health examinations in school and colleges, and in organizations where exercise is taken, such as the Y M C A are of this kind The great diversity of the obligatory examination makes this subject an important one for the medical profession to study and develop

The health client who voluntarily comes to the physician's office is likely to be of the following types, given in the order of frequency first, men between forty-five and fifty-five, women, from thirty to forty, young men and women about to marry, adolescents, in the growing stage, brought in by the parents, and finally, school children (who are rapidly increasing in number) Health clients vary indefinitely, of course, as to sex, age, economic, social, and marital status Haven Emerson suggests the beginning of the health examination should be before birth We may go further and examine the grandfathers and grandmothers as well as the fathers and mothers of the oncoming generation This is the biological point of view It will be seen, therefore, that there are various kinds of health clients of the most diverse classes Each class presents problems peculiar to itelf

Time

There is a great variety of opinion as to the amount of time which should be taken for the health examination For example, at one extreme is the "one minute stripped examination" in which one hundred men employees of a certain steel corporation were lined up, without clothes, and as they passed the physician, each was given an examination of one minute This is a health examination, apparently most inadequate, but it resulted in an astonishing bulk of valuable information From this extreme brevity of one minute, the times increases to fifteen minutes, one-half hour, one hour, two hours, and more, depending upon the purpose in mind, the interest of the physician, and the time and means at the disposal of the client A week in a hospital for observation might not be too long It should be understood that to put a client through all possible tests would probably take six months and would wear out the client It is also the observation of those experienced in the subject that a brief examination by a skilful observer may be worth more than a lengthy inspection with less skill Time alone is not a pledge of merit. It is an element. The time for the health examination will be determined by what the examiner included in his plan As his vision enlarges, the time will lengthen

A plan which has worked well in office practice is the giving of the examination in two parts, several days apart At the first visit the history is taken, the laboratory tests and measurements made, and the organic examination is done Any special tests, such as x-rays, to be taken before the next visit, are then ordered On the second visit, all of the clinical and laboratory data are assembled, all questions are cleared up, the program is decided upon, discussed with the client, and set forth This plan has many advantages, both to the client and to the physician

Summary

Thus the writer has endeavored to discuss briefly the salient points in the first four of the elements of the health examination which cause it diversity They are the purpose and content, the nature of the health client, and the time consumed The other variables, the examiner, the place of examination, the economic aspects, have necessarily been referred to in the course of this discussion which, in the nature of things, must be incomplete These matters are among the many that must be taken into consideration in the planning of health examination forms, records, systems, and campaigns

---

RESPECT YOUR PHYSICIAN

By LE GRAND KERR, M D , BROOKLYN, N Y

RESPECT and reverence are requisites if the better things of life are to be ours Without a preponderance of respect and reverence our perspective of life is warped and its color is drab

Disrespect for a particular law makes its enforcement increasingly difficult Because a large minority of our citizenry have scant respect for the eighteenth amendment, that amendment becomes largely inoperative in such areas

Passive disrespect for peace through emphasis upon the glories of war and the apothesis shown to generals who carry battle to a successful termination, has retarded for generations the possibility of universal peace

If a large part of the medical profession lost the respect which they hold for their patients and the reverence they hold for their profession, it would be a sorry day for public health Fortunately, the great mass of physicians have a well-grounded respect for their patients and a reverence for their health and lives Frequently it is so great that a doctor sacrifices his own life and health for that of his patients

Respect and reverence should beget its kind It is not alone the privilege of the patient to respect and revere his doctor but it is to his distinct advantage to cultivate that feeling This does not mean that one may not seek other medical counsel, it does not even imply absolute faith in all that his doctor does, but it does demand that as a patient he respects all the doctor advises, accepting it as given for his best interests When the patient uses his prerogative of refusing to act upon certain advice, he should do so kindly and not clandestinly This takes no cognizance of that smaller coterie of physicians who feel that when a patient has once consulted them, they have a life time claim upon him and are aggrieved if he consults another, we can dismiss that narrow-mindedness without consideration

Neither does due respect and reverence mean the physicians immunity from ridicule and satire Ridicule and satire are a part of life's amusements They need not, however, influence true and worthy ideals The tawdriest wit with moronic intellect can ridicule anything or anybody Satire, however, is remedial, its object is the betterment of a condition and uses our sense of humor as an agent to accomplish it. Satire may require real genius Under the superficial guise of tearing down, its real and deeper objective is building up

I have viewed with concern the attitude that many men and women take when they discuss a physician They analyze, tear him apart, attempt to see him as he is not This may be permitted the psychoanalyist, who says "Here is an emotion, here a conflict, here a complex, here an inhibition" and they all go to make up this man But for the average person it is wanton destruction Unless you are skilled in gathering up the results of your analysis and orienting them in perfect harmony you are a destroyer Any one can take an automobile engine apart but how few could reassemble it?

See the physician as he is, as he works, as he lives, in other words, you must view him as a person and not a machine Recalling his continual contacts with disease and even death with its constant depressing influence, be charitable toward his moods How advantageous it would be if we could school ourselves to be rigorous in judgment of self and gentle in judgment of our physician Society has need of the family doctor It also has need of the specialist—the genius in medicine The latter is apt to be given too large a place in the high regard and respect of the family, because his work is apt to be more spectacular

It takes a genius to create, to correlate, or to bring any medical advance into useable form The family doctor, however, must desire it and make use of it or no one benefits Of what use is the knowledge of the expert unless the general practitioner, the family doctor, utilizes that knowledge? To illustrate, it took a genius to discover Insulin If that discovery had remained with the genius or had been appropriated by other men working in a special line, diabetics would continue to suffer and die as before But when the family doctors in large and increasing numbers laid hold of the discovery, demanding its fuller production and prescribed it for their patients and thus launched it, that notable find took on efficiency Thus it registered a real and substantial advance in medical science and the prolongation of life. All the medical geniuses and specialists in the United States alone could not have accomplished this It was the great company of family doctors insistently demanding that their patients have something better for health and life that made Insulin of the high value it is

The family doctor works in another practical way, rarely, if ever, getting credit for it A few hundred or a few thousand family doctors demanding something better for their patients results in the production of a producer, a genius in medicine or a specialist who can supply the demand And so the specialist is the creation of the family doctor

In closing, let me ask a simple question How can you expect your physician to make a constant demand for the best that there is in medicine for you, when you deny him the stimulus of a maintained and growing respect and at least a measure of reverence for the things he stands for in medicine?

POPPIS A CODE WORD FOR THE APPROACH TO DIAGNOSIS IN CHILDHOOD*

By JACOB SOBEL, M D, NEW YORK, N Y

THE following remarks are not intended for the trained pediatrician I am presumptuous enough however to believe from my own experience, that they will prove of service in the hands of family practitioners—at least such physicians who are still engaged in what to me has always been and is the broadest, the most humanitarian, the most comprehensive, most self-satisfying, most interesting and the most arduous branch of present day medicine, namely general practice Pediatrics has been defined as the "specialty of the general practitioner" or as Brenneman says "the pediatrician is a general practitioner to the young, a chronologic and not a regional specialist" Considering the fact that a large percentage of the practitioner's routine work deals with infants and children, diagnostic pediatric aids are or should be of great value It is to the general practitioner then that these remarks are in the main directed, although their application by the pediatrician has one saving grace—they will do him no harm

In these days of scientific medicine, one is apt, when working in the forest of laboratories, x-rays, mechanical apparatus, instruments of precision and the like, to lose sight of the fact that he is dealing with a human being who has within his organism much that cannot be recorded or registered by any of the aforementioned adjuvants Perhaps a more fitting title to my paper would be "Back to the Bedside" At the expense of being labelled "old fashioned," I am going to present what I consider a practical, clinical, domestic approach to the sick or ailing child, with a view to establishing a diagnosis After all is said and done, when one is called in consultation to the home of a sick infant or child the paramount interests of the parents center around certain questions which they "put up" to you for an answer The questions are essentially (1) what is the matter with my child, (2) is he very sick, (3) will he recover, (4) how long will it take, (5) are there any complications, (6) will he recover completely, (7) how did he get the disease

Herein lies the difference between private and hospital practice In the former, decisions are expected promptly and at times unqualifiedly, without recourse to laboratory and other aids, while in the latter the diagnosis must often wait upon the elaboration of collateral findings It is in the home then that a clinical sense and judgment are so necessary and that prompt decision is demanded The importance of the clinical side of medicine and the use of our God-given senses are very pointedly emphasized by Dr Irving Roth in his book on Cardiac Arrythmias as follows "Since it is the man and not the instrument who ought to be the final judge, the potentialities of our special senses as simple, useful and readily available means in clinical medicine ought to be developed and utilized" And as Dr Robert Abrahams says very happily "The cardiograph is a fine and delicate instrument but it cannot and should not take the place of the eye, the ear, the hand and the cumulative experience of the examining physician An instrument has no intuitive faculty and no diagnostic instinct"

Diagnosis is the keynote of proper care and treatment Diagnosis of diseases and conditions during infancy and childhood has its disadvantages and advantages over that of adult life While in the early ages a diagnosis must often be made without the assistance and cooperation of the patient and many times against resistance, there is lacking the exaggeration, the antagonism, the hesitancy or side stepping and the prevarication of the adult Furthermore, diseases in childhood are usually single as it were, in that this little body has not as yet been subjected to the many physical, psychic, mental, dietetic and other insults which have become part of the adult, and which result in complicating or coexisting pathology Then too children—at least those who cannot talk—tell no lies, even if they cannot direct your attention to the location of their suffering or ailment or tell of their subjective symptoms

In approaching a diagnosis during infancy and childhood, it has been my experience that errors are more frequently due to failure to think of given possibilities or to examine thoroughly and systematically, than to any lack of knowledge on the part of the physician In other words, the difference between one physician and the other when faced with a given train of symptoms or objective findings, lies in many instances, in being trained to think and examine along systematic lines or to coordinate in his mind certain possibilities Of course, one cannot be expected to unfold in his mind all possible diagnoses But after all, the majority of ailments and disorders in childhood, the every day bedside cases, fall within a somewhat limited sphere, so that, if the physician could have at his command some short cut to thinking of the common or ordinary possibilities, this would serve to focus attention upon them at least And if after such analysis, a diagnosis is not possible, then he could turn his thoughts to the more unusual possibilities or probabilities

While in Vienna during the Summer of 1922 in discussing pediatric material with an American colleague, he mentioned a short code word which

*Read at a Meeting of the Progressive Medical Society New York City, January 8th 1929

he used in his practice to fix his attention upon the common disorders of childhood This idea made appeal to me and since then I have adopted that method, although I have modified and enlarged the code word Surely we all remember how as youngsters the colors of the rainbow were readily brought home to us by the word or mnemonic Vibgyor And surely every physician recalls how in his medical student days he codified or rhymed anatomical and other data, without which—and only too often with—the cramming of the subjects would have been difficult or impossible Who does not remember the mnemonic verse of Oliver Wendell Holmes as a reminder of the sequence of the cranial nerves—

"On old Monadnock's treeless tops
A Finn and Frenchman
Picked some hops"

The code word or mnemonic which I present as an aid in the diagnosis of the more common affections of childhood is POPPIS, not an elegant one I confess, nor one replete with special significance or meaning, but one nevertheless which if adopted and used will, I am sure, lend itself to systematic approach, thinking and examination and will prove useful in arriving at a proper diagnosis

May I repeat that in the presentation of this code word it is not intended to cover the realm of pediatric diagnosis, but it is hoped and expected that with its application and the conditions which it brings to mind, the more usual conditions of childhood as well as some unusual ones will be sought for and diagnosed And while the code may not always fit the disease at hand, opportunity will be afforded for further search and analysis

Taking up this word POPPIS, in the order of its respective letters, we begin with P This letter should recall Pharyngitis and with it the necessity of a thorough examination of the entire oral cavity, throat, nose and neck With this should come a search for such common conditions as coryza, tonsillitis, or membranous exudate nasopharyngitis, adenoiditis, stomatitis retropharyngeal adenitis or abscess, gingivitis, ulcerations, decayed teeth, enanthemata as well as rigidity of the neck and the type of facies Pharyngitis should for purposes of this codification direct attention to many conditions "above the neck" and that this covers a large field in childhood is apparent The O naturally and almost instinctively brings to mind first of all, Otitis All agree that no physical examination of a child is complete without an otoscopic inspection In cases of unexplained temperature rise during the course of the contagious diseases, or with indefinite symptomatology, an otitis will often be found as the etiological agent I have known, and so have you, many a 'touch" of pneumonia, teething, influenza and malaria to clear up spontaneously with rupture of the tympanic membrane. With otitis should come the thought of other conditions in and about the ear otitis externa, furunculosis, eczema, mastoiditis, preauricular adenitis, parotitis and facial nerve involvement

The O should make us ever mindful of the possibility of an Osteomyelitis, especially in cases of prolonged irregular fever for which no apparent cause can be found

The next letter P should draw attention to Pneumonia, Pleurisy and Pericarditis particularly, and to Pertussis, and with them to other allied intrathoracic conditions — endocarditis, enlarged thymus, tracheo-bronchial adenitis, tuberculosis, empyema, atelectasis

Many cases of pericarditis in childhood and of enlarged thymus are overlooked because one does not think of looking or examining for them Certain it is that pericarditis in childhood, either as a primary or a complicating condition, is more common than clinical statistics show, as verified by autopsy findings It is difficult enough and at times impossible to diagnose this condition when one is on the lookout for and thinks of it, but it is increasingly more likely to escape detection when one does not even keep it in mind as a possibility

With empyema an exception must be made in a sense, as to early diagnosis and early treatment. I heard Dr Alexis Moskowitz say, that in the army service, those patients with empyema who came under the supervision of good internists and whose condition was diagnosed early and operated upon promptly, gave a much higher mortality than those who were under the care of less experienced and efficient physicians and who therefore were diagnosed and operated upon later—to their great advantage This may seem paradoxical But the fact is that in metapneumonic empyema experience teaches that operation should wait upon the formation of thick pus and adhesions It is now generally accepted that it is not the empyema, but the early interference and the complicating conditions which kill the patient. If the diagnosis of empyema is made early operative intervention should be delayed, until suitable intrathoracic conditions from the operative standpoint, arise

Typical Pertussis is readily diagnosed—even by the laity Pertussis like coughs, or pertussoid as it is poorly named, often challenges our diagnostic skill This is particularly true and timely in these days when influenza with its persistent, tantallizing, irritating, spasmodic, non-productive cough accompanied at times with vomiting, is so prevalent Since it is in the catarrhal stage that pertussis is so contagious a diagnosis from the family and community standpoints is important and desirable This influenzal cough may last four to six weeks, and may affect several members of the family Corroborative aids in the diagnosis

of pertussis as against influenza are—history of exposure, early morning spasmodic cough, leucocytosis often as high as 30 to 50 thousand, with an absolute lymphocytosis of 60 to 80 per cent of the total number of leucocytes, afebrile character, usual absence of catarrhal chest signs, failure of response to therapeutic measures and finally Petri dish cultures from the bronchial secretion with the recovery of the Bordet-Gengou bacillus ("cough sowing" method) The cough of pertussis may frequently be initiated by suprasternal pressure upon the larynx or trachea or by irritation of the pharynx Pertussis may exist without a whoop

Corroborative of influenza are, history of a previous attack of pertussis, no history of exposure, rise of temperature, evidences of catarrhal symptoms with chest signs, normal blood count, leucopenia or moderate polymorphonucleosis, and the recovery of the influenza bacillus from the bronchial secretion In some cases the diagnosis will eventually remain in doubt

The third P in this code word brings to the fore Pyelitis, Poliomyelitis, and Polioencephalitis, Pyloric Stenosis or Pylorospasm, and with them allied conditions of the nervous and genito urinary system—meningismus, encephalitis, meningitides, kidney and bladder conditions

When poliomyelitis is prevalent the attention of the profession is fixed upon its possible occurrence, so much so that at this time we are apt to err on the side of safety and diagnose other diseases as poliomyelitis In off years, however, when sporadic cases occur, we are apt to lapse, and unless one has the possibility before him, mild and early cases may escape our notice

How frequently does the diagnosis of pyelitis or pyuria thwart us, only because we do not think of it or seek an examination of the urine Days and weeks often pass by in this condition which simulates a variety of diseases often of apparently serious nature, in some instances suggesting the need for surgical interference I should like to add one other thought for the letter P, the thought of purpura, Henochs or abdominal purpura, in cases of vague abdominal pains

The letter I, should bring to mind primarily and immediately Intussusception Many infant lives have been sacrificed because the first doctor called did not think of this possibility Thinking of it is, often enough, all that is necessary to make a diagnosis, and early diagnosis and prompt treatment—surgical intervention—are life saving measures With the thought of intussusception comes the responsibility of ruling out appendicitis, pneumococcic or other types of peritonitis The surgeon should not be blamed for a mortality in intussusception when he is required to operate late The success in treatment of intussusception is in direct proportion to the rapidity with which the diagnosis is made and the promptness with which the patient is referred to the surgeon

The I, should also recall Inanition especially in the newborn with apparently unexplained and often very high temperature, Intracranial hemorrhage in the newborn and general infections

The last letter, S, is of special importance in diagnosis during infancy and childhood and should suggest the possibility of Syphilis, Sepsis, Spasmophilia, and Scurvy, all of which are often undiagnosed because they are not kept in mind during the routine examination Those who have been trained to think of the possibility of Syphilis and Scurvy will diagnose these conditions in *their early stages* far more frequently than is done at present and by instituting their respective specific treatments will bring not only relief to these sufferers but also symptomatic if not pathological cure And repeated convulsions in infancy and childhood, so often attributed to "teething," gastric upset, cerebral disease or what not—mostly what not—will frequently have their origin in a calcium deficiency tetany Thinking of tetany brings with it prompt relief through the use of a calcium salts, parathyroid extract or preferably, in the light of recent studies and observations, through the use of irradiated ergosterol (Vigantol)

Many of the conditions aforementioned are ushered in with fever, and inasmuch as rise of temperature in young children varies within such wide limits and causes, and often remains unexplained in our own minds, it seems to me that a systematic examination is necessary, if not for the establishment of a definite diagnosis, at least for the elimination of certain common and often relatively unimportant conditions

You will note that no attempt has been made here to enter into any elaborate discussion of symptomatology, of diagnostic criteria, or of differentiation, since it is assumed that the application of this code presupposes a critical analysis of the patient's condition Please note, too, that in following the letters of this code word in regular order and applying thereto the diagnostic possibilities, you will automatically or better perhaps routinely, direct your examination to practically all parts of the body, from the head to the toes This in itself will render the overlooking of the more usual conditions less likely

That code words or mnemonics have their place and application in other fields is exemplified by the use of the word SHPSAAA by Dr Louis Faugeres Bishop to designate and remember readily the seven—not fifty-seven—varieties of irregular cardiac action namely—S sinus arrythmia, H heartblock, P premature contractions, S simple paroxysmal tachycardia, A auricular flutter, A auricular fibrillation, A alteration in pulse

It is my feeling based upon a fairly large personal experience and usage that if this code word

POPPIS is carried to the bedside and systematically applied, many errors of diagnosis will be avoided, and therefore many therapeutic and other measures instituted, which will bring comfort, relief of suffering and saving of life to many children

This word POPPIS is, of course, merely an index or guide which I have personally adopted, and I have no doubt but that each one in his own way can or will modify it, or has already done so, to suit his own purposes and needs

The main thing to keep in mind is that in approaching a sick or ailing child it is necessary to proceed in a thorough systematic manner, to examine completely and to formulate in one's mind the various possibilities so that later what proves to be self-evident is not overlooked in the incipient stage With the aid of this or a similar code word I have reason to believe that many diagnostic pitfalls will be averted

It may be argued that this code word, simple as it appears, covers a formidable array of diseases and conditions and that it embraces too wide a field Granting this for the moment, and granting that when first used some items may be overlooked, it will be admitted I think that after its constant use there will arise a coordination and continuity of thought that will become routine and almost automatic.

While it is my desire at this time to emphasize the code word POPPIS, nevertheless I cannot resist the temptation to state that in approaching the newborn I have also adopted a coined code word known as HAASIM as a lead to the diagnosis of certain conditions peculiar or common at this time, or to some of the dangers that lie in the path Hemorrhagic diseases of the newborn, Asphyxia, Atelectasis, Sepsis and Syphilis, Inanition, Icterus and Infections, Mastitis and Meningitides

With a proper approach to the sick child as outlined in this mnemonic or code word POPPIS, there will arise fewer occasions for reproach in your daily routine

Delafield was wont to say that diabetes is one of the easiest diseases to diagnose, if you think of it That was thirty years ago I do not know but what it is quite out of fashion these days to think—in medicine at least It is so much easier to leave it to the laboratory or to special instruments, that we are beginning to suffer from mental inertia or impotence This 'let George do it" policy is leading us far afield from using our God-given senses, and our powers of association, analysis, decision and judgment. It seems almost as if the thinking cap which adorned the heads of those great clinicians of yesteryears has been lost, strayed or destroyed

And so it is that in childhood a careful history, patient inspection, complete, thorough and systematic examination and thinking of possibilities will lead the way to correct diagnosis

Naturally, each one of us when confronted with a sick child gains an impression of the condition at hand It is this medical instinct which is such a wonderful asset in diagnosis And while it is true that it may not be necessary to run the gauntlet of all the conditions embraced within this code word, nevertheless its use will serve as an excellent trainer to systematic and coordinated thinking This in itself would appear to be more than worth while, at least to my way of thinking

Whether you use this code word or some other, or whether you use none at all, it is highly desirable that you develop the faculty of thinking quickly of the various possibilities in the case at hand For my own part I have found that the cultivation of this thinking diagnostic habit can be best attained by the use of some such short cut as this code word—POPPIS

In conclusion, my object has been to present a rapid, practical, systematic working scheme of diagnostic approach for every day bedside practice, particularly in the home, in order to minimize the over-looking of the more common diseases and disorders of infancy and childhood It is hoped that these remarks will open wide a free discussion of the diverse subjects which I have at best only touched upon in the course of my presentation

It is in this sense, gentlemen, and with this object in view that I present POPPIS to you for consideration and judgment

EDITORIAL

NEW YORK STATE JOURNAL OF MEDICINE

Published by the Medical Society of the State of New York under the auspices of the Committee on Publication

Business and Editorial Office—2 East 103rd Street, New York, N Y Telephone, Atwater 5056

The Medical Society of the State of New York is not responsible for views or statements, outside of its own authoritative actions published in the JOURNAL. Views expressed in the various departments of the JOURNAL represent the views of the writers.

AUTUMN MEDICAL NEWS

September has seen the renewal of the older activities of the Medical Society of the State of New York, and the inauguration of new lines of work Progress by the Medical Society of the State of New York is equal to that made by medical schools, research laboratories, and voluntary health organizations The Executive Committee of the Council is considering a wider variety of plans than ever before The county secretaries have held a profitable conference, the committees are expanding their fields of activity, and the District Branches will inspire the members in the local districts Medical news, which is real history in the making promises to be unusually abundant and interesting this fall and winter

COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

No one will deny that humanity has benefited immeasurably as a result of the advances made in public health work In these accomplishments the medical profession has played a most important role For this it has asked no credit Rather it has considered this an obligation, along with other unselfish duties, inherited by a cherished tradition along the principles laid down by the Hippocratic Oath As an expression of their part in this work, the Medical Society of the State of New York has long had an active standing Committee on Public Health Although public health is to-day but a part of the field of preventive medicine, and has properly come under the supervision of governmental agencies, still the physician's part in the larger field has become more important, especially with emphasis now laid *on personal hygiene* Preventive Medicine cannot be separated from curative medicine It is entirely reasonable to say that the former depends on the latter for efficient service The physician therefore because of his endeavors is naturally concerned with preventive medicine, and his community has a right to expect him to act for them as leader and adviser in these matters Realizing that no other agency can so well provide adequate medical service as the medical profession itself, and that this is a most necessary contribution to public health work, our State Society has changed the name of its present standing committee to the more inclusive term, the Committee on Public Health and Medical Education While this committee for several years has been very active along definite lines, its ultimate aim is to have each county medical society do the things it is now doing, and possibly more, in the field of public health and medical education The State Society's Committee urges the co-operation and *support of each county society and welcomes* constructive suggestions and honest criticism from every member

THOMAS P FARMER.

EPIDEMIOLOGY FOR GENERAL PRACTITIONERS

Epidemiology is the most direct and practical application of the principles of preventive medicine It deals with the detection of the origins of cases of contagious disease Every case of communicable disease has a parent and a grandparent, and so on back through a long line of ancestors It is the work of the epidemiologist to follow the tell-tale clues supplied by the patient and to detect the parental origin of the sickness The detective work requires that the epidemiologist shall be familiar with the modes of onset of the disease under investigation and the period of its incubation The investigator must be wise and diplomatic, and able to detect probable truth from deception He must be able to lead up to essential facts through a series of questions which lead the patient and the family to talk freely and to give out clues whose importance the epidemiologist does not disclose until he has secured corrobative facts

To secure epidemiological data requires time, energy, and money to an extent which the average family doctor cannot give, and should not be required to give even if he were so inclined The investigations are community matters, and furnish the best arguments for the establishment of a county department of health which is large enough to support an epidemiologist

The average physician is not trained in epidemiology, and for this the medical schools are responsible Very few medical schools teach their undergraduates the principles of the detection of communicable diseases, and the practical methods of their control Nearly every medical school has a chair of public health or preventive medicine whose professor is expected to teach epidemiology But it is a common fault that the teaching by the professor of medicine is not coordinated with that of the department of public health The professor of medicine, for example, lectures and gives clinics on typhoid fever, its diagnosis, course, and treatment He includes brief statements regarding its origin from food, water, and carriers, and he leaves that subject to the public health professor who deals with that topic weeks or months after the professor of medicine has finished it No wonder the average doctor fails to grasp the principles of detecting the origin of his case of typhoid When the health officer asks him the date of onset of the sickness, he will give the date of his first visit, and will have only a vague idea of when the patient was first conscious of his illness The doctor will nearly always be able to give a clear detailed account of the progress of the sickness since his first visit, but he seldom knows what happened to the patient during the week or month preceding his call

The epidemiologist wishes to know not only the date of onset of illness in a case of communicable disease, he also wants to go back of that date to the time when the patient caught the disease, which, in the case of typhoid, is one or two weeks previous to the date of onset The investigations of a typhoid case, therefore, go back at least a fortnight previous to the first call of the doctor,

and may require visits to a number of stores and dairies, questioning of suspicious neighbors, and securing information from remote places that have been visited by the patient All this is community work, and belongs to the health officer or epidemiologist

However, the family doctor is not relieved of responsibility He is the first to come in contact with the patient, and can secure information before the family and the neighbors become suspicious of quarantines and exposures of infected dairies and water works The patient and his family will talk freely during the early days of a sickness, but are likely to be suspicious and secretive when the neighborhood gossip starts up

How shall the family doctor be instructed in epidemiology? His instruction starts in the medical school There are two ways by which that instruction may be improved

1 The professor of medicine, when he finishes a contagious disease subject, may tell his class to listen carefully to the professor of public health who will give the instruction in the epidemiology of this disease He will also tell the students that they will be expected to stand an examination in the epidemiology of the disease As a matter of fact, this coordination between the two departments of a medical school is seldom effected

2 The second method of teaching epidemiology is that the Dean shall arrange that the professor of public health shall lecture on the epidemiology of a disease as soon as the professor of medicine has given his instruction This is done in at least one medical school

The methods of epidemiological investigation of a common disease are well illustrated by Doctor Laidlaw's article on the epidemiology of a small outbreak of typhoid fever in a rural community, printed on page 1118 in the scientific department of this JOURNAL This article is of practical value to every member of the Medical Society of the State of New York

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Fees to Medical Colleagues —It is a principle of medical ethics that physicians shall treat one another and their families free, yet an up-State doctor was charged by his friend, a prominent New York surgeon, for an operation on his wife, as described in a letter to this Journal for September 1904 The writer said —

"He and myself and wife have been on the best of terms for the last six years During the first three years of our acquaintance I sent him (or referred to him) cases that for his services netted him $3,600 One case he charged the patient $1,500, the second one his fee was $1,000, the remaining $1,100 was distributed more or less over or between three or four patients I did this because I liked him and on account of our friendly relations and not expecting any compensation for it"

After describing an operation performed by the surgeon on the writer's wife, the letter continues —

"After the operation I asked him what his fee would be He hesitated and said 'Well, Doctor, give me what you can afford, but be as generous with me as you can, as my expenses for the last year have been large' I asked him to wait a few days 'Well, two or three days', he said While talking I gave him $50 and said 'Doctor, here is so much to apply on your services' In a few days I received from him the following statement of his account

	$500 00
Discount	200 00
	$300 00

with a foot-note 'Please send check for the amount right away, as I am going abroad and would like to leave my books in as clear a shape as is possible' I replied to his statement, asking him if he did not think his statement was more appropriate for laymen than for a brother practitioner and calling his attention to our relations in the past"

This Journal made the following editorial comment

"The Section of the Principles of Medical Ethics adopted by the American Medical Association in 1903 relating to this subject, Chapter 2, Article II, Section 3, is as follows

"When a physician is summoned from a distance to the bedside of a colleague in easy financial circumstances, a compensation, proportionate to traveling expenses and to the pecuniary loss entailed by absence from the accustomed field of professional labor, should be made by the patient or relatives'

"Hence, it would appear, that the specialist acted in accordance with the principles laid down by the American Medical Association, in making the charge, and, being a reasonable one, it should be paid"

The editor carefully avoided saying what should be done to the surgeon

MEDICAL PROGRESS

Intrinsic Cancer of the Larynx, the Lasting Cure in 76 Per Cent of Cases by Laryngo-Fissure—Sir St Clair Thomson characterizes that type of laryngo-fissure which is limited to "splitting open the larynx and clipping out a cord" as an inadequate and unsurgical procedure for a disease like cancer He resorts to an almost complete hemilaryngectomy, but performed from the inside After the larynx is split open lengthwise one thyroid ala is removed and all the soft tissue internal to it, from its internal perichondrium to the mucous membrane of the glottis, from the ventricular band above to the subglottic space, and from the anterior commissure back to and embracing the vocal process of the arytenoid cartilage This is all removed in one mass With this operation a lasting cure was obtained in 76 per cent of the author's series of 70 consecutive cases Of these patients 63 were male and 7 female Their ages ranged from 31 to over 80 years, though by far the largest number were between 41 and 61 years There were three operative deaths Eighteen patients died of other causes after having lived beyond the three year period without recurrence A number of the survivors have lived to an advanced age and have conserved a useful voice There were 11 recurrences, and 7 deaths from carcinoma elsewhere without local return of the disease With reference to recurrence, Thomson feels little anxiety if the third month passes without any suspicious symptom Early relapses should not be regarded as recurrences, but rather as evidence of incomplete removals By educating the public to pay strict regard to persistent hoarseness, which is the one solitary symptom of laryngeal cancer, and by teaching the profession to appreciate the niceties and necessities of early diagnosis, the number of laryngo-fissures and the proportion of lasting cures will steadily increase, while the need for laryngectomy will as progressively diminish—*Canadian Medical Association Journal* July, 1929, xxi, 1

Carcinophilia—Professor W Weichardt, bacteriologist of the University of Erlangen says that as is well known, the metabolism of cancer cells differs from that of the surrounding normal cells The question arises as to the possible existence of microorganisms which might grow freely on such a selective medium If such were the case the products of metabolism might exert a certain influence over the growth of the cancer cells The author has already devoted years to the quest of such organisms, experimenting chiefly on the tumors of cancer mice Organisms which show preference for cancer cells he terms carcinophilic The avidity of the organisms for cancer cells must lead to an infection of the mass and to some effect upon it, possibly one of lysis The first experiments described are those of inoculating a mouse tumor with cultures of hemolytic streptococci No carcinophilia was evident and the author next proceeded to cultures of *B mesentericus* and the bacillus of timothy grass Both of these gave results more suggestive of specific activity, although the author is silent as to the details He now considers the possibility of preparing antigens from these organisms which may possess not only some therapeutic activity but also diagnostic value The author alludes to the toxic split products which have been described by various authors as resulting from a lysis of the cancer cell and which may exert a hostile action on the organism, but asserts that he is not seeking such an effect nor does he believe in the existence of any specific cancerous hormone (so-called necrohormone) He seems instead to lean to the opinion that any split products formed from the cancer cells may act on the organism at large like ordinary non-specific proteins producing a general reaction—*Münchener medizinische Wochenschrift* June 21, 1929

The Influence of Treatment with Hypertonic Sodium Chloride Solutions in Patients with Acute Abdominal Conditions—In a recent paper R S Anderson and Reed Rockwood reported a marked reduction in the mortality following abdominal operations, from the use of hypertonic salt solution in patients whose blood chlorides were below 260 milligrams as compared with similar cases in which the treatment was not employed They now analyze a series of 90 cases with low blood chlorides in which the intravenous injection of hypertonic salt solution reduced the operative mortality more than one-half In acute cases, such as ruptured appendix with general peritonitis and acute intestinal obstruction there is accumulating evidence to show that the mortality is reduced by delaying operation for several hours and giving the patient a course of preoperative medical treatment The fall in blood chlorides usually parallels the severity of the toxemia, though some patients may have a considerable fall without much evidence of toxemia A comparison of the chemical tests

and may require visits to a number of stores and dairies, questioning of suspicious neighbors, and securing information from remote places that have been visited by the patient All this is community work, and belongs to the health officer or epidemiologist

However, the family doctor is not relieved of responsibility He is the first to come in contact with the patient, and can secure information before the family and the neighbors become suspicious of quarantines and exposures of infected dairies and water works The patient and his family will talk freely during the early days of a sickness, but are likely to be suspicious and secretive when the neighborhood gossip starts up

How shall the family doctor be instructed in epidemiology? His instruction starts in the medical school There are two ways by which that instruction may be improved

1 The professor of medicine, when he finishes a contagious disease subject, may tell his class to listen carefully to the professor of public health who will give the instruction in the epidemiology of this disease He will also tell the students that they will be expected to stand in examination in the epidemiology of the disease As a matter of fact, this coordination between the two departments of a medical school is seldom effected

2 The second method of teaching epidemiology is that the Dean shall arrange that the professor of public health shall lecture on the epidemiology of a disease as soon as the professor of medicine has given his instruction This is done in at least one medical school

This Journal Twenty-five Years Ago

Fees to Medical Colleagues —It is a principle of medical ethics that physicians shall treat one another and their families free yet an up-State doctor was charged by his friend, a prominent New York surgeon, for an operation on his wife, as described in a letter to this Journal for September 1904 The writer said —

"He and myself and wife have been on the best of terms for the last six years During the first three years of our acquaintance I sent him (or referred to him) cases that for his services netted him $3,600 One case he charged the patient $1,500, the second one his fee was $1,000, the remaining $1,100 was distributed more or less over or between three or four patients I did this because I liked him and on account of our friendly relations and not expecting any compensation for it"

After describing an operation performed by the surgeon on the writer's wife the letter continues —

"After the operation I asked him what his fee would be He hesitated and said 'Well, Doctor, give me what you can afford, but be as generous with me as you can, as my expenses for the last year have been large' I asked him to wait a few days 'Well, two or three days', he said While talking I gave him $50 and said 'Doctor, here is so much to apply on your services' In a few days I received from him the following statement of his account

	$500 00
Discount	200 00
	$300 00

with a foot-note 'Please send check for the amount right away, as I am going abroad and would like to leave my books in as clear a shape as is possible' I replied to his statement, asking him if he did not think his statement was more appropriate for laymen than for a brother practitioner and calling his attention to our relations in the past"

This Journal made the following editorial comment

"The Section of the Principles of Medical Ethics adopted by the American Medical Association in 1903 relating to this subject, Chapter 2, Article II, Section 3, is as follows

"When a physician is summoned from a distance to the bedside of a colleague in easy financial circumstances, a compensation, proportionate to traveling expenses and to the pecuniary loss entailed by absence from the accustomed field of professional labor, should be made by the patient or relatives'

"Hence, it would appear, that the specialist acted in accordance with the principles laid down by the American Medical Association, in making the charge, and, being a reasonable one, it should be paid"

The editor carefully avoided saying what should be done to the surgeon

is found Seventy-five such patients were included in this study and 24 died, one-half of them succumbing to heart failure Obese patients are poor surgical risks Cardiac patients, excepting those with syphilitic aortitis or advanced coronary disease, are not likely to die suddenly during operation Patients without heart lesions, either by clinical or pathological standards, are more likely to die unexpectedly as a result of anesthesia than are those with demonstrable heart disease Auricular fibrillation increased the danger of death from operation in arteriosclerotic cases only from 3 4 to 37 5 per cent but in a small series of rheumatic heart cases the increase was from 8 8 to 22 2 per cent Thyrocardiacs with auricular fibrillation do better under operation for hyperthyroidism than any other group with this arrhythmia, because of the favorable effect of thyroidectomy on the heart The suspected cardiac patient should be studied from the medical and surgical viewpoints before operation, instead of when he is *in extremis* from which there may be no relief So long as surgeons consider patients "especially unsafe" their future in the hands of the surgeon is relatively bright.—*Surgery, Gynecology and Obstetrics,* July, 1929, xlix, 1

Is There a Genuine Active Immunity to Syphilis?—W Kolle and R Prigge attempt an answer to this question on a basis of research made at the Chemotherapeutic Research Institute in Frankfurt The question is of great importance with special emphasis on late manifestations of the metaluetic type Immunity to syphilis has in general been regarded as ordinary infection immunity with resistance to new infection based on the presence of residual spirochetes in the tissues Let sterilization once come about, whether spontaneous or the result of treatment, and reinfection readily follows But recent research, especially in the United States (Chesney, Kemp), has shown that rabbits cured of syphilis by early intensive salvarsan treatment may undergo a superinfection—that is, a theory of superinfection is in harmony with the facts This phenomenon is seen in a certain number of cases only and the act of superinfection may be unaccompanied by symptoms Two sets of rabbits were inoculated by Kolle with respectively homologous and heterologous tissues containing spirochetes and in each of the series the positive results exceeded the negative ones in number The assumption of Chesney that an active immunity exists to syphilis is, in Kolle's opinion shown by these experiments to be unwarranted, and the old clinical opinion that there is no true active immunity to syphilis is borne out There is of course a chancre immunity The symptomless superinfection develops in treated animals not only in the early but also in the later stages The old view that syphilis immunity is an ordinary infection immunity is therefore not shattered by the work of Chesney.—*Deutsche medizinische Wochenschrift,* lv 24, June 14, 1929

Incipient Tuberculosis—Dr J Heimbeck, an internist of Oslo refers first to the possibility of showing on a Röntgen plate the early subclavicular infiltrate so characteristic of tuberculosis in youth In regard to Pirquet positives, these are rare in Oslo in early life but become more and more frequent as the child ages Nurses tested with the Pirquet when they enter upon their service at the General Hospital show negative reaction in 52 per cent, while only a very few of the positives develop the disease in later life A study with the Röntgen ray of a large number of negatives from the training school for nurses showed at first that all were negative, but as a result of a follow-up 9 showed later the subclavicular infiltration The freedom from all evidence of older infection left no doubt in the author's mind that these patients were infected from without In these negative Pirquets the reaction became strongly positive and various general and local symptoms developed Of three cases reported, all of the patients showed erythema nodosum as a manifestation, and the author stresses the importance of this symptom from the diagnostic standpoint To the original shadow of the subclavicular infiltration were added numerous other evidences of pulmonary mischief The first patient showed scattered spots over the right lung area, the second showed the same and a doubtful apical pleuritis, and the third patient had the same shadows as patient No 1 As a result of his experience the author exculpates latent infection in childhood as the cause of tuberculosis during the 15-25 year period, save in rare exceptions These youthful tuberculous subjects are manifestly infected from without, when the negative Pirquet becomes strongly positive for the first time The subclavicular infiltrate is a true primary lesion which is followed by fever and other evidences of toxinemia, such as erythema nodosum. The lung mischief tends to diffuse itself on the infected side.—*Klinische Wochenschrift,* June 25, 1929

Diagnostic Value of the Isolated Pupil Symptoms in Visceral Syphilis—Professor R. A Luria of Kasan has studied a series of more than 250 cases of visceral syphilis and distinguishes between monovisceral and plurivisceral forms, although he himself has seen only the latter In an entire series of cases he has found isolated pupillary symptoms which comprise a variety of manifestations, as anisocoria, rigidity, and certain minor anomalies Anisocoria occurs in about 2 per cent of normal individuals and is also seen in diseases other than syphilis However the impor-

in this group for chloride, non-protein nitrogen, and carbon dioxide capacity shows that the chloride is the most delicate indication of the toxemia and may or may not be accompanied by a rise in the non-protein nitrogen The carbon dioxide capacity tends to rise until the rise in non-protein nitrogen occurs, when it begins to fall, often resulting in an acidosis rather than an alkalosis For practical purposes only the blood chloride estimation need be made, for intravenous medication may safely be given in the presence of clinical signs of toxemia without resort to the laboratory At first only 1 or 2 per cent sodium chloride solutions were used, but now the authors are practically always using 5 and 10 per cent sodium chloride in 10 per cent glucose In their entire series of injections only one reaction has occurred, and that was not severe The only precaution insisted upon is that the water used in making solutions must be freshly distilled, and that no solution should be kept longer than three days In the illustrative cases cited the amount injected was usually 500 cc —*Surgery, Gynecology, and Obstetrics,* July, 1929, xlix, 1

The Bloodmaking Action of Large Amounts of Fresh Fruit Juice —Mm G Mouriquand and A Leulier and Mlle Schoen, in dealing with this theme, mention the ancient belief in the antiscorbutic power of fruit juices and especially those of the citrus fruits In more modern times credit for this result has been given to the vitamin C contained in these juices, and not alone ordinary scurvy but other forms of hemorrhagic disease and resulting anemia have benefited as well as forms of paraplegia, while the same substances exert a prophylactic action More recently these juices have been held to benefit anemias directly, increasing the number of red cells and hemoglobin, although it is admitted that the conditions thus benefited may belong to the avitaminoses C The authors have tested these juices in both experiment and the clinic—in the latter they have especially studied the treatment of simple anemias of early childhood of the type sometimes called alimentary Guinea pigs were submitted to ordinary fasting tests and to deprivation of vitamin C, and the blood counts were followed up for each series In each an anemia developed but much more rapidly when the vitamin was withheld In general inanition the animals received lemon juice which evidently held back the development of the anemia In vitamin starvation the fruit juice soon brought the number of red and white cells to the normal The conclusion is reached that in avitaminoses, including anemia, large doses of lemon juice suffice to bring the blood cells up to the normal count, while in inanition and underfeeding (too few calories) the same substance is equally efficacious in overcoming anemia —*Bulletin de l' Academie de Médecine,* June 11, 1929

Egg Idiosyncrasy —Bruno Bloch and J A G Prieto report at great length a case of this idiosyncrasy with a discussion of the role of allergy in the genesis of eczema and other dermatoses The case in question was nominally an eczema in a child with egg idiosyncrasy, manifested as follows ingestion of an egg caused first of all a generalized urticaria followed by fever, diarrhea, and miliary erythema When egg was applied directly to the skin, the latter having first been scarified, an erythemato-urticate eruption appeared in a few minutes If the egg were applied to the intact skin, there appeared at the end of 24 hours an epidermo-vascular reaction which presented all the characteristics of an eczema Not only the egg of the fowl but the flesh of the latter and the egg of the goose caused these phenomena The antigen was found to be dialyzable and was therefore not a protein. It has been shown that in such cases of idiosyncrasy a reaction takes place between the antigen and a sessile antibody—in other words an allergic reaction The eczematous portion of the reaction may or may not be transmissible by the passive route The conception which makes of eczema an allergic reaction which corresponds to that in asthma, serum sickness, etc., would necessitate a contact between the allergen and a specific antibody fixed in the cells of the epidermis This view is rendered plausible by a series of clinical and experimental data It should not be thought of as applying to the great majority of eczemas —*Annales de Dermatologie et de Syphiligraphie,* May, 1929

The Heart in Surgery —Howard B Sprague has analyzed the results of surgery on 170 cardiac patients to discover, if possible, what types of heart disease influence prognosis He finds that age is the most important factor in mortality Two-thirds of the deaths occurred in patients over the age of 50 Of 14 patients dying under the age of 50, syphilitic heart disease was present in 3, rheumatic heart disease in 6, Pick's disease in 2, with hypertension, obesity plus hypotension, and unknown heart disease in 1 each Of the 170 patients 42 died during or following operation, a gross mortality of 24 7 per cent, but only 5 patients died suddenly on the operating table Of the 42 deaths only 22 were due to causes directly referable to the heart though cardiac disease may well have made some of the others more susceptible to the pathological conditions from which they died Of 47 patients with rheumatic valvulitis and normal cardiac rhythm only 4 died Patients with rheumatic heart disease and normal rhythm without congestive failure can be operated on with little danger It is in the group of degenerative heart disease, arteriosclerosis with or without hypertension, that the greatest mortality

LEGAL

INSANITY—EFFECT ON THE MARITAL CONTRACT II

There are three parties to the marriage contract—the husband, the wife and the State Thus the parties to the marriage may not by their own acts change the marital status We will consider in this editorial the right of either spouse to annul their marriage on the ground of incurable insanity

Prior to March, 1928, the statutes of this State did not afford any relief to either husband or wife where, subsequent to the marriage, either of them became incurably insane, and this too despite the fact that the insanity may have continued over a great period of time

The plight of a man or woman who find themselves bound by the marital tie to one incurably insane, makes out an appealing case for judicial relief There is an old legal maxim, however, that "Hard cases make bad law" In a matrimonial situation, it is impossible to divorce any individual case from the welfare of society as a whole The stability of the family as a human institution must be preserved and zealously guarded, in order that the welfare and happiness of the offspring of the marital union be preserved Any proposal, therefore, to annul a marriage based upon the incurable insanity of one of the parties must, of necessity, be considered in the light of all the other factors and conditions to which reference has already been made

The problem was solved when the Legislature amended the Domestic Relations Law in 1928 by adding to Section 7 thereof a new subdivision which provided that a marriage is free from the time its nullity is decreed by a Court of competent jurisdiction, at either party thereto

"Has been incurably insane for a period of five years or more, provided, however, that if the marriage be annulled on the ground of the insanity of the wife, the court, before rendering judgment, must exact security, to be approved by a judge of the court, for her suitable care and maintenance during life Provided further, that judgment annulling a marriage on such ground shall not be rendered until in addition to any other proofs in the case, a thorough examination of the alleged insane party shall have been made by three physicians who are recognized authorities on mental diseases, one of whom shall be the superintendent of a state hospital for the insane, the other two to be appointed by the court all of whom shall have agreed that such party is incurably insane and so reported to the court'

In your counsel's opinion, this is a just and humane law, as protection is afforded against either collusion between the parties or the desire of one party to rid themselves of the other on a mere pretext For example, it is to be noted that the statute provides that

1 The insanity must be incurable,

2 It must have persisted for a period of five years,

3 The alleged insane party shall be subjected to a thorough examination by three physicians who are recognized authorities on mental diseases, one of whom shall be the superintendent of a state hospital for the insane, and the other two to be appointed by the Court,

4 No judgment of annulment shall be rendered unless the opinion of the three physicians who have examined the alleged insane person is unanimous that such person is incurably insane,

5 Adequate provision is made in a case where a husband seeks to annul his marriage, for the support and maintenance of the wife, and such support and maintenance is guaranteed by getting from the husband proper security

The question as to how much a husband who seeks an annulment under this statute should pay for the support and maintenance of the wife and for how long, as well as the nature of the security to be given therefor, was the subject of a recent decision The learned Court gave a just and reasonable interpretation to the statute in this respect The decision reads in part as follows

'The questions presented to the court for determination are what is the adequate amount required for the suitable care and maintenance of the defendant and how the payment of the same shall be secured The first question is quite analagous to the question so frequently presented in actions of divorce of fixing alimony A like method would be applied of ascertaining the means of the husband and the requirements of the wife in her present condition This may be presented in the shape of affidavits As to the method of securing payment it must be noted that the payment to be secured is during the lifetime of the defendant If a bond is given it must be for the joint lives of the parties As the defendant would lose her right to support by the death of her husband if the marriage were not annulled, I think that a bond limited to the joint lives, instead of to the life of the defendant would meet the requirements of the statute Nothing less than this would do so I do not think that the bond of the husband to pay for the support of the defendant during her life would be sufficient unless it be under exceptional circumstances

tance of this is much less than that of the Argyll Robertson pupil, when occurring as an isolated phenomenon The author does not refer merely to typical cases of the latter but also includes sluggishness of the pupils One or both eyes may be involved Naturally one thinks of neurosyphilis in these patients as an explanation of the pupillary phenomena, in which case the association with visceral disease might be a mere coincidence The author, however, is prompt to show that the anomalies in question occur when neurosyphilis is *quite absent* Thus in company with others he has seen them in syphilitic ulcer of the stomach and presumably in other locations, although for some reason he always adduces syphilis of the stomach to illustrate visceral syphilis But the association of neurosyphilis with visceral syphilis is of unusual interest and importance in these patients and the two types of late syphilis are often associated in peculiar ways Thus we may find a specific radiculitis in certain cases, suggesting that neurosyphilis may itself give rise to visceral mischief The rationale of pupillary anomalies in these cases is in fact not apparent and may indicate that the disease has directly attacked the vegetative nerves, although some invoke a low grade of meningitis It must be borne in mind that the Argyll-Robertson pupil has been seen in chronic alcoholism, nicotinism, and diabetes At present we can only state that the anomalies in question are often suggestive of visceral syphilis —*Deutsche medizinische Wochenschrift,* June 21, 1929

Aerophagy and Pneumatosis Ventriculi — R Isenschmid of Berne states that air swallowing assumes a number of clinical forms, one being vertigo or syncope The air may accumulate in the stomach or colon The subject is ignorant of the swallowing but when he is observed the larynx may be seen to move up and down or saliva may be swallowed Our exact knowledge of air swallowing however, dates from the use of the fluoroscope, which shows every step of the process of air accumulation and expulsion Nervous men and women suffer most Pneumatosis ventriculi is a generic term for a stomach distended with gas of which aerophagy is but one of the causal factors We know little enough of the nature of air swallowing or why it gives rise to burdensome symptoms in some and perhaps none at all in others With most people accumulation of gas in the stomach leads to eructation Many explanations have been offered and it seems certain that there are different mechanisms involved in different cases Some air must be swallowed with meals, but this is probably expelled by eructation in the normal subject In the author's experience, however, most patients swallow the air when they are not eating In one case perhaps, an increased flow of saliva causes incessant swallowing, while in another the swallowing is a nervous manifestation Presumably *an atonic stomach* favors accumulation and retention, but many patients seem to suffer from the opposite condition of hypermotility Does treatment throw any light on the symptom? Sometimes the air can be extracted by introduction of a stomach tube or more air may be swallowed until the stomach is forced to expel it Nerve sedatives (bromides) are often of such value that the role of nervousness as a causal factor is made manifest Bismuth and charcoal are of some value which seems to show that there is a factor of irritability of the gastric mucosa A dietetic treatment hardly exists in the author's opinion —*Schweizerische medizinische Wochenschrift,* June 8, 1929

Vaccination Encephalitis —Prof A Eckstein, of the pediatric clinic at Düsseldorf, gives a concise summary of our knowledge of this compilation which dates in a way from 1922 although it was known before then Evidence accumulates that it is one of a group of encephalitides of which the most conspicuous is the epidemic form known at first as sleeping sickness, which has since manifested itself as a protean disorder, occurring no longer in epidemic waves Encephalitis may complicate measles, chickenpox, and mumps, but all cerebral complications must not be set down as encephalitis and the author would exclude from this group the cerebral manifestations of scarlet fever and whooping cough In regard to the very first record of vaccination-encephalitis it is of interest to state that it dates from Freud as far back as 1897, at which period this author was making an extensive study of the cerebral palsies of childhood, before he had become interested in psychoanalysis Eckstein gives long accounts of the cases in England and Holland where the incidence has been much higher than elsewhere Scattering cases have been reported from Czechoslovakia, Austria, Sweden, Poland, Bulgaria, and Italy As for Germany the author has made an intensive search of the records and has found no less than 89 cases, of which at least 11 developed before 1922 with one as far back as 1912 No cases are mentioned in any continent but Europe, America being still immune, and data fail for Eastern Europe (with the exception of Bulgaria) Generalization is still very hazardous, for on a basis of the English and Dutch statistics it appeared that the danger period was from 3 to 13 years, but an analysis of the German figures seems to show that immunity before and after that term of years is an illusion and that there is in reality no special period of predisposition or immunity While the complication is not to be underrated it would be far worse to intermit vaccination or make it optional —*Klinische Wochenschrift,* June 18, 1929

NEWS NOTES

AMERICAN CONGRSS OF SURGEONS

Nearly every county in New York State is represented in the membership of the American College of Surgeons which will hold its nineteenth annual clinical congress in Chicago, from Monday to Friday, October 14-18 The clinical program of the Congress fills ten pages of the August issue of *Surgery, Gynecology, and Obstetrics* and includes clinics in the principal hospitals of Chicago, given by visiting doctors as well as local physicians

Special attention is to be devoted to the demonstration of modern methods in the treatment of fractures At the Cook County Hospital a special fracture clinic will be conducted each morning and afternoon, and at many of the larger hospitals plans are being made for a complete showing of the methods and end-results in this special field which forms so large a part of the surgical work in this great city

A conference on traumatic surgery is planned for Friday morning and afternoon A report of the Committee on Traumatic Surgery will be given, and an open forum will be conducted

An added clinical feature of importance at this year's session will be provided by a series of clinics to be given by outstanding surgeons of the American continent on Tuesday and Wednesday afternoons beginning at 2 o'clock in the grand ballroom of the Stevens Hotel Among those who will give clinics are the following George W Crile, Cleveland, John B Deaver, Philadelphia, John M T Finney, Baltimore, Charles H Mayo, Rochester A symposium on pernicious anemia will be presented by Charles A Elliott, Chicago, George H Whipple, Rochester, New York, C C Sturgis, Ann Arbor, Michigan, and William P Murphy, Boston

The annual business meeting of the Fellows of the College will be held on Thursday afternoon The annual convocation will be held on Friday evening when the 1929 class of candidates for fellowship will be received

The feature of Monday afternoon's program will be the practical demonstration of a model staff conference by one of the local hospital groups, together with a discussion of the entire subject of staff conferences

A symposium on the prevention of infection and a round table conference on administrative problems, admission of patients, the clinical laboratory, the social worker, etc, are important features of the second day's program and will include a practical demonstration of an administrative conference

On Wednesday morning there will be a joint session with the Association of Record Librarians given over to a symposium dealing with the efficiency of case records

These are only a few features of the annual Congress It is hoped that a goodly delegation of Fellows from New York State will be present

DISTRICT BRANCH MEETINGS

The meeting of the Sixth District Branch will be held on September 27th, instead of the 25th, as announced on page 1031 of this JOURNAL of August 15th The dates and places of meetings, so far as they have been arranged, are as follows

Fourth District Branch, Saratoga Springs, Thursday and Friday, September 19th and 20th

Third District Branch, Kingston, Saturday, September 21st

Sixth District Branch, Cortland, Friday, September 27th

Seventh District Branch, Clifton Springs, Saturday, September 26th

Eighth District Branch, Buffalo Thursday, October 3rd

Fifth District Branch, Watertown, Thursday, October 17th

First District Branch, Yonkers Friday, October 25th

THE NEW DIRECTORY

Copy for the Annual Medical Directory of New York, New Jersey and Connecticut was sent to the printer in August, and the reading of the proof should be completed by the end of September

Each year there are a number of physicians who delay sending their new addresses telephone numbers etc until all the proofs have been read and the pages made up It is therefore very important if there are any changes in your record for the Medical Directory that you send them at once to the Medical Society of the State of New York, 2 East 103rd Street, New York

LONDON LETTER

LONDON, AUGUST 28, 1929

Post Vaccinal Encephalitis The occurrence of a further fatal case in London (the seventh this year) of encephalitis following prophylactic inoculation against smallpox has excited much public interest and the matter has been raised in the House of Commons It is now agreed in medical circles that these cases of encephalitis are due to the vaccination, but in what way is not clear It has been suggested that the introduction of vaccine makes more active or reduces resistance to bacteria which are latent in the body, others suggest that some impurity in the lymph is responsible In this country lymph prepared by the Government can be obtained only by the public vaccinators, and the private practitioner has to obtain his lymph from medical supply agents who may obtain the lymph from less well controlled sources At the British Medical Association Meeting now being held in Manchester, opinion was general that the lymph obtained from private firms varies very much in potency, one medical man stating that a public vaccinator using Government lymph has had no failure in 21 years, whereas with lymph obtained from the best firms in London, only 25 per cent had been successful An official of the Ministry of Health stated that Government lymph could not be supplied to private practitioners because no records would be kept of the number treated or the results The public vaccinators have to keep such records, and the latest figures show that of 576,589 capillary tubes, each containing sufficient lymph for one person, supplied in one year, 98 6 per cent gave a successful result He advised all those requiring to be vaccinated to go to the public vaccinator The question, however, as to whether any cases of post vaccinal encephalitis have followed the use of Government lymph has not yet been answered, but a full enquiry is to be demanded in the House of Commons and some important facts may come to light

'Ragging' by Medical Students On June 20th an anti-vivisection meeting at the Caxton Hall, Westminster, was broken up by an organized body, presumed to be medical students, and some very rough horse-play resulted A protest to Scotland Yard has resulted in a letter being written by Viscount Byng, the Commissioner of Metropolitan Police, to the principal medical schools asking the authorities to warn students against the practice, and to appeal to them for better behaviour It is curious that it has taken the police so long to act, for there is no doubt that 'ragging,' among medical students at least, has been for a long time on the decline Except for the usual exuberance at the Rugby Football cup-ties and the traditional "enmity" between University College and King's College there has been hardly a 'rag' of any importance since 1919 when "Pussyfoot" Johnson, to the dismay of the participants, lost his eye At my old hospital—St Bartholomew's—it has long been decided, with that curious unanimity which only youth can display when "good form" is in question, that 'rags' were not 'quite,' if one may use a modern cliche. It was not ever so, and I well remember a gorgeous 'rag,' when, on a particularly snowy day in mid winter, it suddenly occurred to some cheery students that the immemorial custom of the City police to use the "Square" as a short cut between the Henry VIII Gateway and Little Britain should no longer be recognized The first policeman to appear was greeted, much to his surprise with a volley of snowballs He whistled for assistance and very soon quite a battle was in progress It was conducted with the greatest good humor on both sides and neither claimed a victory, but many windows were broken, and repairing the damage cost us quite a lot But it seemed worth it at the time! High spirits and the pursuit of medicine have always been associated, and it is interesting to speculate on the causes which change the somewhat irresponsible student into the grave and altogether exemplary practitioner I believe it would be found that the 'raggers' are more in the early years of studentship and that the feeling of responsibility soon settles upon them, as they are brought into actual contact with disease, suffering and misery But a little buoyancy does no harm, and I hope the authorities will convey Viscount Byng's caution in the way it is meant!

Lavender Time Now through the hot and dusty streets of London comes the Lavender cry, oldest and last of the cries of London A haunting melody, always heard so far away and yet so near, bringing before us visions of some well-remembered garden, some grassy walk between the nodding "spikes," some scent, some rare memory Well! Well! Another fortnight, and then

H W Carson, F R C S

PUBLICITY WORKERS

Columbia University will conduct a course on 'The theory and technique of modern publicity work." The *New York Sun* of August 29 comments editorially on the course and says

"Perhaps it was coincidence, but the announcement by the publishers of the Red Book that this city has 4,338 varieties of business was followed in a few hours by the assurance of Columbia University that its course in "the theory and technique of modern publicity work" will be continued.

'Surely there are many lines of industry which have not yet obtained the services of expert "publicists," "directors of public relations" and plain, old-fashioned press agents The desks in this office, which creak under the barrage flung from myriad mimeographs, have yet to feel the weight of propaganda from the pretzel factories, the overall laundries and the makers of pipe-bending machinery and carpet tacks These and a thousand other industries obviously need their place in the sunlight

"Strangely, more propaganda is employed for the sake of the ideal than for the advancement of the real If you set up a new league of nations, a new brand of ethics, a new method of ridding the world of sin, pain or debt, a purely philanthropic scheme for conserving the forests by turning them over to a power company, or a holy plan to crush the power companies by putting the government in the hydroelectric business, you must have a red-hot 'director of public relations' Six days he toils and on the seventh he shoots his product, marked 'released for Monday, February 31,' at the newspaper If when it is read it falls into the basket to the accompaniment of a groan, what of it? One more editor has failed to grasp a great idea"

Even the sanctum of the NEW YORK STATE JOURNAL OF MEDICINE is the depository of enough pieces of "Publicity" on health alone to keep every issue of the JOURNAL filled in quantity if not in interest

---

MARIHUANA

The New York *Sun* of September 4 has an editorial on marihuana, a cactus of the Southwest called mescal button or peyote by the Mexicans It is used by the Indians and Mexicans as a narcotic whose effects are those of haskeesh, or hemp The *Sun* says

"Except those 'with the proper credentials' little is to be learned concerning marihuana in respectable quarters Governments and libraries are afraid of it, and justly The belief is probably that those who know nothing about it will not be tempted to fall prey to its ugly fascination"

This will be news to most doctors

CITY INCINERATORS

The disposal of garbage and rubbish by burning has at last been placed on a scientific basis in which the production of smoke and odors may be prevented to such an extent that many of the large hotels dispose of all their household waste in their own incinerators in their cellars

The *New York Sun* of August 29 discusses public incinerators in the following editorial

'With the completion on October 1 of the last of the incinerator units for Brooklyn the whole output of garbage and rubbish in that borough will be disposed of by scientific appliances This gives Brooklyn five plants for incineration of garbage and rubbish, and fourteen incinerators that destroy only rubbish

"Each of the three new plants has a capacity of 500 tons a day, of which 75 per cent is garbage and 25 per cent rubbish, including what is called trade wastes Geographically the new plants are well situated One is on the Gowanus Canal at the foot of Hamilton avenue, South Brooklyn, one on Newtown Creek, Greenpoint, and one close to the Paerdegat Basin of Jamaica Bay Not only do the furnaces and equipment of these plants follow the latest designs, but showers and rest rooms are provided for the employees The capacity of the five incinerators is 371,000 tons of garbage a year, which allows a margin of 48,000 tons over the quantity collected in 1928

"It is not easy to find sites for incinerators on Manhattan Island or in the Bronx and Queens Neighborhood prejudices are active despite assurances that these plants will create no nuisance Incinerators have become a public necessity and it is urgent that plants be installed at waterside stations in all the boroughs not now so equipped When this is done there will be no New York city garbage fouling the city's own shores and those of New Jersey, Long Island and along the borders of the Sound"

THE DAILY PRESS

FASTING CLUBS

Early in the summer there came to the Journal office a four-page pamphlet describing "The World-Wide Fasting Movement, the most basically spiritual movement ever undertaken on earth," organized by the Fasting Clubs of Chicago for world-wide regeneration" This cult holds That the Hypnotizing and Re-education of the world's subconscious mind by holding the Perfect Vision, is a reality"

The promoter, G H Aron, offers to send free instructions which include the following subjects

The technique of fasting

Twenty-one methods of quickening elimination during fasting

What to think about during the fast

Thirty-eight magic words defined

Aspects of the individual in the perfect vision

The state in the new civilization

Extracts from opinions of great men

The pamphlet contained copies of advertisements in the *Chicago Daily News* offering free lectures—no collection taken—on some of the objects to be attained through fasting, among them being the following

Governmental purchase of farm land until that left in private ownership should be only sufficient to produce what the people consume

Choice of the President of the United States on the basis of scientific character analysis

Outlawry of war by fasting (evidently based on Napoleon's statement that an army fights on its stomach)

Possibly the object of fasting club is contained in the following statement

"Dr Aron and Staff of Fasters will leave for the Millson 1000 acre private estate in the Rocky Mountains, on July 22nd for the "Ideal Fast,' the fast to hunger, lasting from forty to ninety days"

Now, for the second half of the story *The New York Times* of August 29th contains the following item from Lyons, Colorado

"On a cot in a tent the lifeless and withered form of a Chicago art model and member of a cult that came to the wilderness of Peaceful Valley to seek "youth, truth and health" was found today, a victim of starvation

"Instead of youth and health Chris Solburg, 40 years old, found death

"Solburg was one of a party of thirty members of a Chicago health cult who, a month ago, under the leadership of Dr George Huntley Aron, came to Colorado seeking a place where they might practice their health tests, including fasting

"Sunday Solburg, who had completed his fast of thirty-one days, began eating solid foods His fast had reduced him from 160 to 85 pounds After consuming several sandwiches his friends said that he was in agony All day Monday he remained on his cot and yesterday he was inert, refusing to converse with other members of the cult who were fasting

"The Chicago cult received considerable publicity when ranchers reported that its members were running around Peaceful Valley without clothes, taking sun baths Authorities demanded that they at least wear sun suits

"With Solburg's death only a few members of the Chicago cult remain at the camp and, excepting one person, they are reported to have quit fasting"

ADVERTISEMENTS NEXT TO READING MATTER

Advertisers often specify that their announcements shall be placed next to reading matter, and this JOURNAL tries to accommodate them However, an article in the *New York Herald Tribune* of September 3, describing the ninth International Congress of Psychologists, said

"Dr Harold E Burtt, of Ohio State University, reported on experiments made for the reader's reactions to "flats" and "standards' in advertising

"Dummy magazines were made up in pairs—each containing twenty-five pages of reading matter and twenty-nine full page advertisements In one of the dummies the advertisements were grouped in two "sections" with the articles in between, while in the other the same material was used but after five initial pages of reading matter, alternate pages were devoted to advertisements

"The subject submitting to psychological scrutiny looked through the dummy for ten minutes and was tested for his observations He was then given the second dummy Preliminary results indicated no outstanding superiority for either methods"

many health books are apt to do, in the mind of the reader

And it answers many questions which the laity are constantly asking—notably the differences between the optometrist, optician and oculist or eye surgeon, and the importance in using drops" in testing for glasses, etc.

The book is divided into four parts Part One is devoted to a discussion of the Mechanism of Sight, including the question of glasses, Part Two, when the mechanism gets out of order, including the commoner external diseases, Part Three, the Eye in Middle Life and Beyond, with description of cataract, iritis and glaucoma, and Part Four, on Eye Inheritances

The author is to be congratulated upon covering the field so thoroughly and so entertainingly in such brief scope

E. C. PLACE

DISEASES OF CHILDREN Second Edition, Edited by HUGH THURSFIELD, D M., M A, F R C P., and DONALD PATERSON, M D, M R C P Octavo of 1106 pages, illustrated New York, William Wood & Company, 1929 Cloth, $13 00

This is a large one volume treatise on Pediatrics with almost 1100 pages of text. It is the second edition of a work first published in 1913, and edited by Sir Archibald E. Garrod, the late Frederick E. Batten, and Hugh Thursfield This present edition was edited by Hugh Thursfield and Donald Paterson, both on the staff of the Hospital for Sick Children, Great Ormond Street, London Naturally, the lapse of time between the first and the present edition caused the work to be looked upon as something out of date in these days of rapid advancement in the field of Pediatrics

The present edition has been brought thoroughly up to date, and it may claim, with some justice, to be the best single volume on the subject in the English language. The array of Pediatric authorities to be found in the list of contributors is most imposing and the selection of the writers for the individual subjects has been a happy one. While there can, at the present time, be no great difference of opinion between Pediatricians in England and in America, one is struck, in reading this book, by some of the minor, though noticeable, differences One notes in the section on the 'Feeding of Infants and Children" that protein milk of various types which the writers, Dr Cautley and Dr Paterson agree, is very popular in Europe and America is little used in England Another point of difference between the procedures in the two countries is in the use of castor oil, not only as a purgative, but as a corrective in cases of gastro-intestinal dysfunction 'Celiac Disease' which is taken up by Dr Reginald Miller is described as being an intolerance of fat with carbo-hydrate indigestion as an entirely secondary symptom. In this country, it is generally agreed that this condition involves an intolerance of both fat and carbo-hydrate. Another striking thing is the apparent difficulty of getting clean milk from tuberculin tested cows which, of course, in this country is no longer difficult. Little's Disease or Cerebral Diplegia is not admitted to be caused in every case by cerebral hemorrhage at birth, but two of the factors admitted are, health of the mother during pregnancy and the degeneration process dependent on some toxic condition or defective vital endurance.

It is refreshing in these days of multi-volume sets on Pediatrics to come across a single volume work which covers the field thoroughly and yet does not sacrifice completeness and accuracy for condensation

WM HENRY DONNELLY

PHYSICAL THERAPEUTIC TECHNIC. By FRANK BUTLER GRANGER A B M D Octavo of 417 pages illustrated Philadelphia and London, W B Saunders Company, 1929 Cloth $6 50

This is the best and most simply written book which has as yet been published on this subject. Dr Granger was a noted specialist in Physical Therapeutics and was not given to exaggeration. In the preface he states that this work is not intended for specialists but rather for the general practitioner who wishes to know what to do with various types of physical therapeutic apparatus. He stresses the value of massage and feels that the office assistant of a physician attempting to do physical therapeutics should be first of all a well trained masseur The book has a short simple chapter on electrophysics which is the basis of a great deal of physical therapeutics and should be mastered by one attempting to do this work. This is followed by a description of the currents used in medicine with their physiological effects and methods of use. He next describes the electro magnetic system with the effects of the various rays on the human system There is a short chapter on hydro-therapy and one on massage

He outlines a hospital department of physiotherapy and describes its relations with the other services This is followed by chapters on certain diseased conditions in which he has found physio-therapeutic methods of treatment to be of value, and an index of diseases with the methods that he has used in the treatment of them

He states that the methods used are private not official and are not endorsed by any council, medical school or hospital, but are the results of his own experience.

No one attempting to start using physical therapeutic methods of treatment can afford to be without this book

CHARLES F McCARTY

SURGICAL PATHOLOGY By CECIL P G WAKELEY, F R C S, and ST J D BUXTON, M B, B S Octavo of 904 pages illustrated New York, William Wood & Company, 1929 Cloth, $12 50

This is a splendid book particularly for the surgeon, who by becoming a better pathologist becomes a much better surgeon.

The cuts are excellent, the reading matter is clear and interesting

The work covers the entire field of pathology from the surgical standpoint Enough histo-pathology is presented to clarify the pathological anatomy where this is desirable

M E MARTEN

RECENT ADVANCES IN SURGERY By W HENEAGE OGILVIE M A, M D 12mo of 461 pages, illustrated Philadelphia, P Blakiston's Son & Company, 1928. Cloth, $3 50 (Recent Advances Series)

This book of 461 pages with 108 illustrations concerns itself with the proven advances made in general surgery This does not mean that the text of the work depicts any thing brilliantly new or phenomenal By the time a new procedure has proven its value, it is already old However, in its 16 chapters the author and his collaborators have sifted out of the mass of newer things surgical in nature, the ones which have proven to be of value and of constructive interest

To enumerate the individual advances found in the book would require a complete paraphrase Suffice it to say that the reviewer has found it well worth his while reading its contents He recommends it to all those interested in surgery

MERRILL N FOOTE.

THE TECHNIC OF LOCAL ANESTHESIA By ARTHUR E. HERTZLER, A M., M D Fourth Edition Octavo of 284 pages illustrated. St. Louis, The C V Mosby Company, 1928. Cloth $6 00

Although this book presents the standardized technic of local anesthesia it is a personal work, reflecting vast experience and special skill Indications contraindications and difficulties are thoroughly covered. It is a safe guide for the workers in this field who do not require an encyclopedic treatise including yesterday's refinements

A. C. J

BOOK REVIEWS

THE CHILD OF CIRCUMSTANCE The Mystery of the Unborn By ALBERT WILSON, M D Octavo of 420 pages, illustrated. New York, William Wood & Company, 1929 Cloth, $6 00

All those interested in abnormal conduct, and more particularly in criminology, will find this book a most interesting one Wilson gives much space to the management of criminals in various countries, and praises especially the methods used in Holland and Belgium

The author does not believe in determinism, and is rather scant in his treatment of psychoanalysis In fact he is a strong believer in the organic basis of misconduct He thinks that poorly developed pyramidal cortical cells favor criminal conduct, and suggests that the law should recognize this theory This is a long way from the Freudian or behavioristic theory of conduct

He is motivated by a broad humanitarianism He has an interesting chatty style It is because he presents his theories in a different sort of way that makes them of value to the student of abnormal conduct For even though one might not agree with all of his views, the reader will derive benefit by studying this book by Wilson

JOHN F W MEAGHER

NEUROSURGERY Principles, Diagnosis and Treatment By WILLIAM SHARPE, M D, and NORMAN SHARPE, M D Octavo of 762 pages, illustrated Philadelphia and London, J B Lippincott Company, 1928 Cloth, $11 00

This compact volume in five parts treats of a highly specialized field of surgery and its press work suggests more substantial information for the average medical practitioner than the contents actually warrant

Part I This section of the book includes Tumors, Abscess Injuries With or Without a Fracture of the Skull Hydrocephalus, Cranial Deformities, Indications and Technique of Special Examinations and Tests, Indications and Technique of Cranial Operations

Despite the work on tumors in recent years by men of Harvey Cushing's experience, this discussion apparently ignores the fact that many gliomas show a low degree of malignancy and that removal of the growth may be followed by absence of symptoms for several years Here, a subtemporal decompression is recommended for such conditions

In the chapter on Brain Abscess, the author stresses the use of the subtemporal decompression in most cases of temporosphenoidal abscess, and emphasizes that exploration for the abscess should take place through the subtemporal route and not through the infected mastoid field

Birth injuries are treated at some length, quoting the author's experience with this phase of the subject, including specific data as to frequency and advising early and repeated lumbar punctures to prevent cerebral spastic paralysis

Hydrocephalus, Cranial Deformities, Indications and Technique of Cranial Operations are discussed in turn without the addition of any original aspects of these phases of the subject

The section on Surgery of the Spinal Cord by Norman Sharpe suggests early laminectomy for spinal injuries producing compression of the cord, also laminectomy in certain types of multiple sclerosis

The surgical treatment of early, selected, cases of purulent meningitis, localized, and associated with mastoid disease, should have a subtemporal decompression performed on the corresponding side of the head

The end results of Neurosurgery are finally outlined in a more forceful than convincing style.

H G DUNHAM.

GLEANINGS FROM GENERAL PRACTICE. By DAVID TINDAL M D 12mo of 209 pages New York, William Wood & Company, 1929 Cloth, $2.50

In this book the author gives especially to young physicians, some counsels on professional conduct and upon medical subjects There are chapters on the young practitioner, on professional conduct, on medical treatment and on the care of children and the aged. There are notes on cookery and sick room administration and over 200 prescriptions favored by the writer Some of these contain too many ingredients in one mixture to be popular at present

W E MCCOLLOM

AIDS TO PSYCHOLOGY By JOHN H EWEN, M.R.C.S., Eng, L.R.C.P Lond 16mo of 166 pages New York, William Wood & Company, 1929 Cloth, $1 50

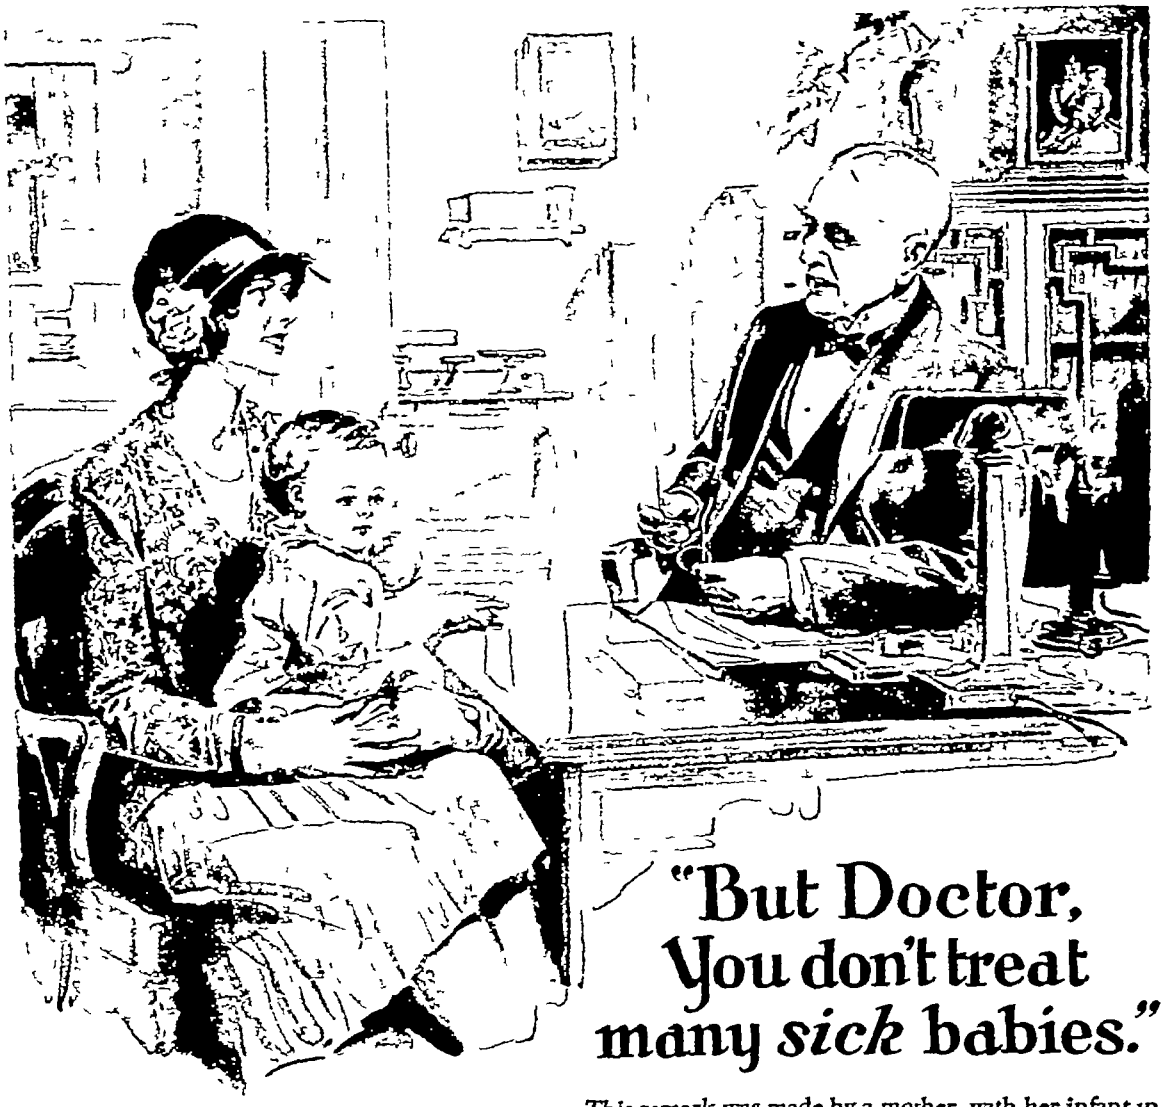
This vest pocket edition serves as an aid for students who are particularly interested in psychological medicine. It is intended to be used only after more exhaustive volumes on psychology have been studied It deals primarily with the more orthodox schools of psychology, paying little attention to Freudian mechanisms It serves well the older static psychology, and should be of considerable help to the student in reviewing his psychology, as it covers the subject quite well

IRVING J SANDS

DIABETES AND ITS TREATMENT By FREDERICK M ALLEN, M D 24mo of 98 pages New York and London, Funk & Wagnalls Company, 1928. Flexible leather, thirty cents (The National Health Series—Edited by the National Health Council)

This little pocket-size volume is as complete and well-written a treatise for the layman as has been published Aside from its usefulness to the diabetic, its cultural aspects should be of value to the average intelligent reader who wishes to increase his general fund of knowledge

WILLIAM S COLLENS



CARE OF THE MOUTH AND TEETH By HARVEY J BURKHART, D D S, L L D 24mo of 45 pages, illustrated New York and London, Funk & Wagnalls Company, 1928 Flexible leather, thirty cents (The National Health Series—Edited by the National Health Council)

A timely well-written booklet covering the subject in a self-explanatory manner Read it, digest it recommend it to your patients A worth-while contribution to a layman's dental education

LEONARD KOHN

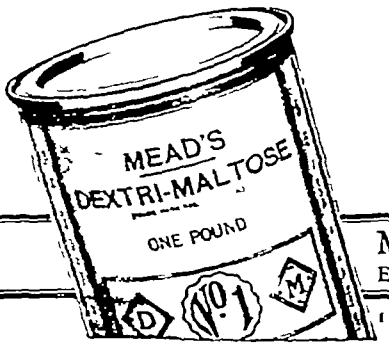
WHAT EVERY ONE SHOULD KNOW ABOUT EYES By F PARK LEWIS, M D F A C S 24mo of 70 pages, illustrated New York and London, Funk & Wagnalls Company, 1928 Flexible leather, thirty cents (The National Health Series—Edited by the National Health Council)

One could wish that this well-written little booklet of 70 pages could be read in every home in the country With only occasional lapses it tells the story of ophthalmology in simple terms, which are readily understandable to the lay mind—no mean accomplishment. It captures the interest of the individual in an important phase of health, without exciting alarming ideas, as

"But Doctor, You don't treat many *sick* babies."

To the woman pictured in this interview, it somehow seemed that in a case of artificial feeding, intestinal disturbances were an inevitable necessity—that these were dread diseases which in some vague, mysterious manner, baffled all efforts to prevent and whose correction lay in the drastic administration of drugs

This remark was made by a mother, with her infant in her arms, as she discussed her own case with her physician Paradoxically enough, because her physician was a successful infant feeder, he gave promise to lose standing in her estimation.



The Doctor's reply was illuminating to this mother—"*We don't treat many sick babies because we feed more well babies properly*"

So modern feeding practice seeks first to preserve the infant's health rather than correct nutritional disturbances. And in this it is eminently successful. What this patient did not realize was that the physician needed her confidence and co-operation.

The dangers of carbohydrate fermentation are greatly minimized, weight gains with sound body turgor are easier to secure by the use of Mead's Dextri-Maltose in fresh cow's milk or lactic-acid milk mixtures.

It is readily assimilated by the infant and is supplied the doctor with different salt contents. No. 1 with sodium chloride 2% for normal cases, No 2, salt free and No. 3 with 3% Potassium Bicarbonate for constipated infants.

DOCTORS' CARDS IN STATE JOURNALS

Several State Journals, among them being those of Indiana and Michigan, carry the cards of physicians in their advertising columns The practice is often criticized and is decreasing But the August *Journal of the Tennessee State Medical Association* records editorially the approval of the advertising cards and says

"Some effort was made last year to increase the number of pages of advertising in the Journal by running a Directory of Physicians The plan was approved by the Board of Trustees at the meeting held in February, 1929, but it was thought wise not to push the matter until the House of Delegates of the State Association acted upon it The matter was submitted to the House of Delegates and approved by that body at the meeting held in Jackson, in April, 1929, so that all the steps have been taken to secure the approval of all concerned

"There can be no objection raised on ethical grounds In fact, a number of very high class state journals are running such a directory

"Members of the Association are now in position to decide for themselves whether they want the directory or not You have all the facts before you

"The following is a sample of what will be run It is taken from the *Journal of the Indiana State Medical Association*

"Phone Main 2290, Residence, Humboldt 1401
C E Orders, M D
General and Abdominal Surgery
350 Bankers Trust Bldg, Indianapolis, Ind

"It will be noted that the card shows the name, the location, the 'phone number and the specialty of the doctor

"The reasons for running such a directory have multiplied in recent years A number of younger men in the profession who are not well known throughout the state have equipped themselves to do special work There is no good reason why men engaged in special work should not make the fact known to the doctors of the state No statements beyond those run in the card will be permitted, of course

"The cost will be on the basis of a full-page ad in the Journal for twelve months, which will be $18 00 per year per card running ten cards to the page We will not run any cards until a sufficient number of contracts to run a page have been signed Payment for running the cards would be made semi-annual in advance

"We do not expect to use high-pressure salesmanship in building up this directory, nor do we expect to place it on the grounds of charity

"The financial condition of the Association, as shown by the last audit, is sound The roll of members at the present time is equal to the largest enrollment we have ever had at this time of year Owing to the work that lies before the Association for the next eight months the expenditures will be heavy These expenditures will not be of a current nature Next year will be the year for the centennial celebration and no one at the present moment can anticipate the cost of all the efforts that are to be made in making this event a success

"Members of the profession who are interested in space in the directory are requested to write the Journal at once and a page will be started as soon as ten contracts have been signed"

SECRETARIES' MEETING IN MISSOURI

The August issue of the *Journal of the Missouri State Medical Association* carried an account of the twenty-first annual meeting of the Missouri Society of Medical Secretaries which was held in Springfield on May fifteenth, with forty-two secretaries present The first address was given by Dr J H J Upham of Columbus, Ohio, who said

"Another good thing it seems to me is to get our county societies interested in public health problems As you know, that it a burning question We are having all kinds of uplift work going on and all the various societies are becoming active, and if you can get your society to take up problems of this sort the members will take a prominent place in the community and be consulted on such matters You will feel a sense of pride in getting the members to come out, and they will feel they have important matters to discuss at the meetings, and also that they have a recognized place in the community when health problems are brought up

"Then every once in a while have a social

Invalids and Underweight Children Thrive on BabyGain

Pure, fresh milk from healthy, Tuberculin-Tested cows, modified and powdered.

While BABY GAIN has proved an ideal infant food, containing all the elements in correct proportion as in human milk and as easily digested, it will equally benefit older children and invalids of all ages with impaired digestion

In such cases the physician may increase the proportion of powder and water, according to the individual case, to 5 or even 6 measures of powder in 8 ounces of water

This is a nourishing meal in itself and has the advantage of accurate balance and easy digestion It will be assimilated in most cases where whole fresh milk is not tolerated by the patient

The only fat in BABY GAIN is the natural butterfat in the pure, fresh Tuberculin-Tested milk from which it is made

meeting—a social meeting with something to eat. It is curious how having a little something to eat will bring out a good attendance. You notice what a good attendance there is tonight. It gives the members a little period of relaxation and helps them meet their fellow practitioners, it brings about a better feeling There is a little of the old feeling that goes away back to the Arabs, that when you eat salt or break bread with a man you are friends So when we eat together often there is a lessening of prejudice, a frank discussion of various things that bring about a better understanding"

Dr Upham praised the wives of the doctors, but said

"In Ohio we do not have a Woman's Auxiliary We like to think it is because we are doing the work so well that it is not necessary, but I think it is because the women are so busy trying to clean up poor old Ohio politically that they have not gotten around to it But if they do take hold they will stir things up in a medical way because you cannot stop them"

Dr Frank I Ridge, President of the Missouri State Association, discussed programs as follows

"The program committees in many instances are carried away by the P T Barnum psychology of these days They want to see plumes and brass harness, and it has gotten to the point where no society thinks it can have a good, instructive medical program unless they have lantern slides, instead of good argument and debate upon real medical problems They can sit there and go to sleep while the slides are being shown, and then come around afterwards and say how they enjoyed your presentation of the subject, and they don't know any more than the dead what you did show But they have had a good magic lantern show They are fascinating to the eye, and we will have to admit that sometimes slides are very helpful"

Dr J M Singleton, Kansas City, continued the discussion of programs, and said

"Having open meetings where the public is invited is all right But the main thing is to arrange a program for the year and try in that time to cover the field of medicine pretty generally Another thing of importance is variety in any single program With the secretary of the Society and the chairman of the entertainment committee getting behind the program committee and the chairman of the entertainment committee and with the other members taking an interest in the preparation of papers and reviews of advancing medicine I think the field should be pretty well covered No man can read all the medical literature, and the medical society should have a place where new things are discussed The society should feel itself responsible

owner, had for its sole aim the handling of telephone calls for the physician who subscribed to the service while he was away from his home or office A certain number of people would even call this bureau for a physician and allow the owner to send any physician he wished to give the call Indeed, through the influence of the name, Physicians Service Bureau, many people even from outside Milwaukee County began to ask advice of this bureau as to the merit, standing, and ability of the various physicians and surgeons in the community"

A further complication was publicity of the purchase of a pulmotor by the Milwaukee Fire Department and the resulting calls on the fireman for its use in every sort of emergency The article continues

"With these facts before them, the directors of the Medical Society of Milwaukee County decided that the medical profession itself could remedy the existing situation in some degree by acquiring the full ownership, control and operation of the Physicians Service Bureau Such operation by the medical society itself, would then make it possible to offer to the public an instantaneous, efficient medical service to the public in time of emergency It would offer to the individual practitioner on the other hand, a sort of clearing house where he could be assured that his clientele would receive medical service during his absence or in an emergency by fellow-physicians whom he has selected beforehand

"This result alone, however, in the opinion of the directors, was not sufficient. It was equally necessary that there be some active contact between the general public and the medical profession To accomplish this, a full-time Executive Secretary was appointed, who, while conducting the Service Bureau, would also protect the legitimate interests of the profession in its relation to the public"

BETTER HEALTH FOUNDATION OF CALIFORNIA

The August issue of *California and Western Medicine* has an editorial description of a new corporation called "Better Health Foundation" which was formed by the union of several other public health organizations The editorial says

"Articles of incorporation have just been filed and the officers of the Foundation are Dr Reginald Knight-Smith, president, Dr Langley Porter, first vice-president; Dr James W Ward, second vice-president, Dr Hartley F Peart, executive vice-president, Dr John Gallwey, treasurer, Dr Charles D McGettigan, comptroller Directors Drs William Palmer Lucas, Walter F Schaller, O D. Hamlin, Dudley Smith, W P Read, Ferdinand Stabel, Harold Brunn

over a period of years for the covering of new things in medicine in the form of bringing them before the society for discussion A symposium on any subject is not usually well attended The men interested in that one thing attend—the others pass it up In the cities the men can take advantage of libraries The American Medical Association provides any amount of articles, and you can get literature from libraries in St. Louis and in Jackson County—all the literature you want The society should take advantage of that in the preparation of programs and in the study and preparation of papers I think it would be wise to have clinical demonstrations We have a good many cases demonstrated before our county society and I think that could be developed in the smaller centers"

The meeting closed with a discussion of State Legislation

FULL-TIME COUNTY SECRETARY

The Milwaukee County Medical Society has recently adopted the plan of employing a full time Secretary Commenting on this plan the August issue of the *Wisconsin Medical Journal* says

"It has been well demonstrated in recent years that the problems of the individual doctor are increasingly giving way to problems of the entire profession As this is true today, so must it be evident to one who studies these problems, that their future solution will only be found in group action under a wise leadership

"It is with this in mind that we feel that the members will never have cause to regret this step and that the near future will bring them returns, both material and those not as easily demonstrable, that will more than justify their unanimous vote"

A news item in the same *Journal* describes the events which led up to the appointment of the full time Secretary A survey of the medical profession of the county led to conclusions described as follows

"The physicians of Milwaukee County were in great need of a central nurses' directory, to enable them to secure nurses within a short time with a minimum of effort

"It was also apparent that organized medicine in Milwaukee County needed aggressive rather than quiescent policies in protecting the legitimate fields of the profession

"This survey further disclosed that for a period of about five years there has been conducted in Milwaukee County a privately owned and privately managed enterprise known as the Physicians Service Bureau This business, although conducted in a perfectly ethical manner by its

and Celestine J Sullivan, director of information service

'Dr W B Coffey, chairman of the executive committee, aptly describes the Foundation as 'a philanthropic clearing house—the first non profit non-stock corporation organized for the health profit of the public'

"The corporate seal of Better Health Foundation crystallizes its mission in these words 'For the Commonwealth'

"The Foundation will take over Better Health Service, hospital betterment work and other activities of the League for the Conservation of Public Health, and expand the consructive program of health education Authoritative, well-directed educational publicity, such as the League has been conducting for the past eleven years, is one of the most effective weapons we have in curbing preventable diseases and reducing the patronage of quackery The practical value of scientific medicine and all allied sciences is equivalent to the amount that the public understand and will accept and practically apply

"The great advances of science can be applied in the most effective way for the promotion of health and the reduction of preventable disease by the cooperation of all factors—the agencies of scientific medicine, the public, and an efficient central information service such as is now established by Better Health Foundation The awakening of the public to the need of protecting their bodies and minds and to bring the messages of scientific medicine to the daily attention of the average newspaper reader is a service of great importance Health and disease conditions are not only matters of personal importance, but they exert far-reaching influence upon the collective social and economic life of the state. Unused knowledge is useless Continuous public health education is necessary so that practically everyone will learn what scientific medicine can do for them and how to apply its scientific lessons in making life healthier, happier and more efficient

"Eight different classes of membership are provided for Better Health Foundation, embracing persons whose education, good judgment and practical experience in various specialized fields of health conservation and scientific research work equip them to undertake impartial studies and fact-finding surveys for the Foundation, owners, executives and administrators of institutions, corporations interested in facts pertaining to disease and accident prevention in industry, hospitals interested in hospital betterment, etc All interested in any phase of this constructive health program will be given an opportunity to contribute small or large amounts to help carry on the beneficient work of the Foundation All of the money raised, whether from donations of

Cheplin's
THE ORIGINAL
B. ACIDOPHILUS MILK

Accepted by the A.M.A. Council on Pharmacy and Chemistry

An Active Culture of B. Acidophilus of Proven Intestinal Habits

Prepared under the direct supervision of Dr H A Cheplin, the pioneer in Acidophilus therapy

Years of continued use of this product has definitely established its value in

CHRONIC CONSTIPATION **DYSENTERY and resultant**
MUCOUS COLITIS **INTESTINAL TOXEMIAS**

The freshness and potency of Cheplin's B Acidophilus Milk is assured through **Distributing Milk Companies** in all principal cities, making daily deliveries

If you will send us your name and address, we will mail free sample of our product copy of 28-page brochure on B Acidophilus therapy giving list of 31 important references together with name of dairy delivering Cheplin's B Acidophilus Milk in your vicinity

CHEPLIN BIOLOGICAL LABORATORIES, Inc
Syracuse, N Y

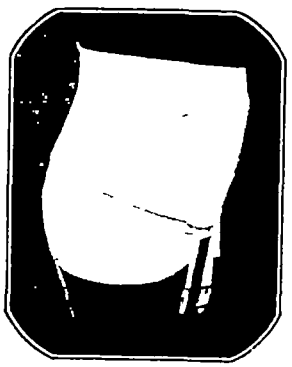
Prescribing the Remedy— *and taking it . . .*

IT is not enough to prescribe for the patient—the medicine must be taken to be resultful. That is why modern pharmaceutical art concerns itself so thoroughly with making the remedy not only purer, more efficient, but palatable and easy to take as well.

If you are not already using

ALKA-ZANE

the systemic alkalizer for the treatment of acidosis



some day you will try it and become readily convinced not only of its effectiveness but of its palatability as well

Try it Liberal trial quantity is at your service

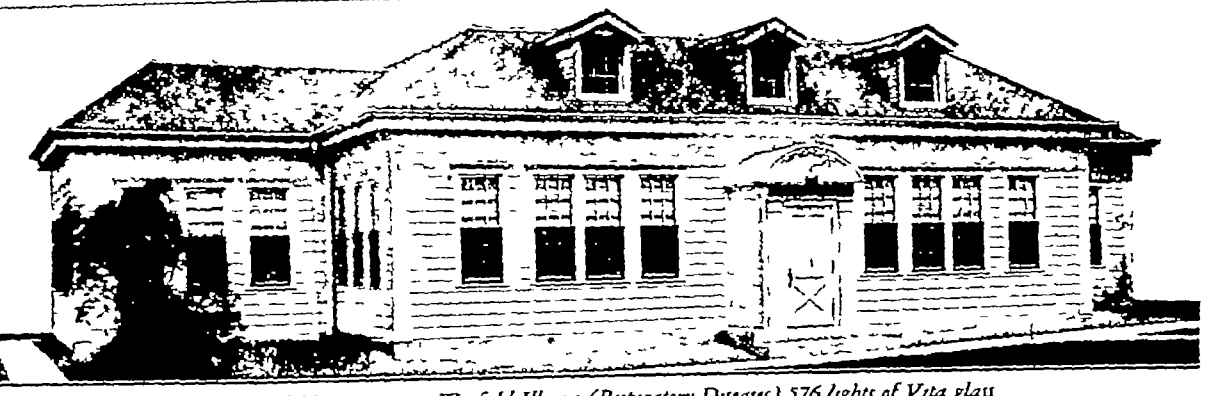
philanthropists or dues of members, will be devoted to constructive work as none of the directors as such receive any compensation, salary or profit in any form

'Philanthropists, in many striking instances, have given great sums of money for purposes, institutions and organizations that are no longer practical Having in mind many frozen funds and inoperative endowments that were established for transitory needs and that unwise bequests and endowments may create dangerous problems instead of conferring benefits on a community, the officers of Better Health Foundation will supply accurate information to philanthropists who desire to make endowments, bequests, donations or contributions to enterprises, institutions, agencies or special work of practical value in solving vital problems, so that the gift may be serviceable and not impractical, so that foresighted philanthropy may meet scientific and economic developments and keep step with ever-changing standards, customs, laws and living conditions The basic virtue of this plan is that it establishes a disinterested and competent body to whom men with money to give may turn for impartial information"

MEDICAL NEWS SERVICE IN WISCONSIN

The August issue of the *Wisconsin Medical Journal* has an editorial on the weekly news service of the *State Medical Journal,* which says



"The good which comes to earnest practitioners from a conference with men of their own profession is but a whisper unless their knowledge can be disseminated The weekly news service of the State Medical Society of Wisconsin is the vehicle by which the Wisconsin public learns what science can do for the suffering It is so highly regarded that other states copy its articles

"The good to be accomplished in disseminating knowledge through the channels of the press has a double purpose It gives the lie to the pretentions of the quack and *it affords an enlightened* hope to the suffering But the good can be increased many fold by the active cooperation of every physician"

This weekly news service is described by Dr H M Strang, in the annual report of the Committee on Health and Public Instruction as follows

"Three hundred and seventy-five daily and weekly newspapers of this state are now receiving the weekly news story issued under the auspices of this committee of your Society The clippings of this story in type from any one week make a newspaper column over 150 feet in length

Chicago-Winfield Sanitarium, Winfield Illinois (Respiratory Diseases) 576 lights of Vita glass

Open Your Windows *to* Health

*Glazed with Vita*glass, they welcome the sun's vital aid to your patients*

IN cloudy and clear weather, in snowtime and Maytime, an incessant but unheard tattoo beats upon the windows of your hospital. It is an assault of the ultra-violet rays—a friendly assault—that must not be repulsed by the blind and barricaded windows of the past.

Remove these antiquated barriers For now you may replace them with windows of Vita glass, and thus bring to weakened human bodies the energizing power of the sun, the mighty unseen factor in truly modern hospitalization

You have heard of Vita glass But do you know

of the graphic tests it has undergone, at the expert hands of the U S Army Medical Corps and the Council on Physical Therapy of the American Medical Association?

Did you know, for instance, that Vita glass has achieved definite results in the prevention and cure of rickets, and the hastening of convalescence And that 350 hospitals and sanitoria have already installed Vita glass in ward windows and solaria.

We should like to have you read the record as it has been made by Vita glass and reported by many of the world's leading scientists We believe it must impress upon you the importance of completing your hospital equipment with this new and invaluable contributor to sure and rapid convalescence

Will you, then, mail us the coupon below, that we may put this authentic information upon your desk at once?

Vita glass Transmission Constant After Few Weeks Exposure

The biological tests made with seasoned Vita glass indicate that it produces anti rachitic results and normal growth in rats and chickens

There are two ways to test the transmission of health window glass—the physical method and the biological method. The former measures the quantity, and the latter both the quantity and the quality of transmission.

Vita glass has been subjected to many accelerated weathering tests by the U S Bureau of Standards, by Professor Stockbarger of the Massachusetts Institute of Technology and many other physicists. These scientists confirm the fact that the solarization (weathering or seasoning) of Vita glass takes place very quickly, and that after a few weeks of actual use, its transmission of the health giving ultra violet light becomes constant.

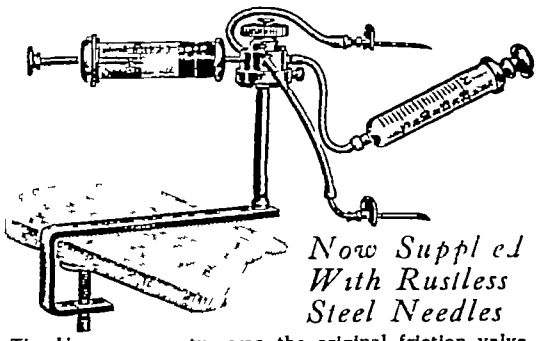
DIPHTHERIA PREVENTION

Its Practical Application

Toxin-Antitoxin (*Lederle*) has immunized many thousands of children against diphtheria which has lasted for nine years, and may continue throughout life



Toxin-Antitoxin (*Lederle*) is especially useful for immunization of the following groups, except immediate contacts

(1) All children from 6 months to 6 years of age
(2) School children.
(3) Adults whose daily work might expose them to diphtheria

Toxin Antitoxin (*Lederle*) and Schick Test (*Lederle*) are readily available through your druggist

(*Continued from page* 1172—*adv xviii*)

"While not every story deals with a major health problem, all are aimed to acquaint the people of the state with the services that are to be had at the hands of the family physician in the prevention and cure of disease. Each story is designed to give valuable information with which the non-medical public would not be acquainted in any other manner It is hard to estimate the numbers of readers, but it is apparent that they number hundreds of thousands each week

"While no address of the Society is given for questions or literature because the funds do not permit of this work, nevertheless the Society receives countless letters from readers asking for additional information and literature

"It will interest the members to know that this service is so well considered in other states that it has already been sold to Minnesota, for a very nominal sum and its extension to several other states seems possible

"We recommend the continuance of this public service and its extension for magazines in the state should additional funds become available."

DISCIPLINING PHYSICIANS IN CALIFORNIA

The August issue of *California and Western Medicine* contains an article on Disciplining Licensed Practitioners, given by Dr Percy T Phillips of Santa Cruz before the Annual Congress of Education held by the American Medical Association on February 20, 1929, in Chicago The part of special interest to physicians in New York State is that relating to California, which says

"During the last ten years the Board of Medical Examiners of California have issued 198 citations Of these forty-seven citations have been dismissed Eighty-five licenses have been revoked, eight have been suspended and fifty-one have been placed on probation During this time we have restored four licenses unconditionally and nine with probationary limitations The courts have restored seven licenses We have thus been reversed but seven times on writs of review Such statistics are local and uninteresting except that they indicate a definite policy on the part of the California board to apply discipline in its fairest and broadest sense Not only does discipline imply correction and punishment, but education, instruction, training and culture We hold that medical boards, not only from the standpoint of their licensing function but also because of their duty to maintain discipline, should take a lively interest in all matters of medical training and education"

AUGUST ANNIVERSARIES

Minnesota Medicine, the *Journal of the State Medical Association*, has a President's page. Dr J T Christison writing the President's page in the August issue says

'August is to be noted as a month fraught with much of interest and value to the profession of medicine In August, 1897 Sir Donald Ross first announced his far-reaching discovery of the fact that the dapple-winged mosquito was the carrier of malaria In August, 1904, General Gorgas began his epoch-making assault on the mosquitoes of the canal zone, making this area a safe place for the white man to live, basing his activities upon Sir Donald's researches and this other species of mosquito responsible for the spread of yellow fever was virtually exterminated and instead of a death rate of seventy-five per cent of the workers who labored in the canal zone for nine years under the French, the death rate was reduced to almost zero from this scourge In August, 1914, just seventeen years later, the canal zone was completed and opened for shipping It is interesting to note that in August 1774, Priestly a famous chemist of his time, discovered oxygen He called it pure air from the fact that when inhaled it produced a feeling of exhilaration and vastly increased the vigor and volume of a candle flame"

DOG'S SELF-DEFENSE

If you step on a dog's tail in Michigan the dog has no right to bite you This is what the August issue of the *Journal of the Michigan State Medical Society* states in the following article

'The Supreme Court in a recent decision held that a dog does not have a right to defend itself by biting even though stepped on by a person

This interesting case has direct bearing on the spread of rabies The facts were that a person accidentally stepped on a dog that was minding its own business, and the dog in turn bit the party who stepped on it The party who was bitten asked damages of the owner of the dog The dog owner claimed that the dog had been assaulted and had a right to defend itself in a truly canine way

"These two differences of opinion were taken to the Circuit Court and later to the Supreme Court The majority of opinion of the State Supreme Court was to the effect that the law of canine self-defense does not relieve the owner of the liability for injury to the person who inadvertantly steps on the dog

"Experience in many places is to the effect that the occurrence of rabies in dogs who receive the innoculation of canine antirabic virus is very small as compared to that in dogs that have not been so treated"

BASIC SCIENCE EXAMINATIONS IN WASHINGTON STATE

The August issue of *Northwest Medicine* contains the following note

"Results of Basic Science Examination At the Washington basic science examination, held last month at Seattle, sixty-three doctors of medicine were examined, of whom fifty-nine were successful and four failed Four osteopaths were examined, all of whom passed Seven chiropractors took the examinations of whom two were successful and five failed Four representatives of other drugless healer cults were examined but all failed In order that these successful applicants may be licensed to practice, each must pass an examination before his respective board of examiners"

This item is interesting on showing how the cultists compare with physicians in the branches which are preliminary to the actual practice of medicine

A NEW PRODUCT

Dr Upsher Smith and his sons are glad to be able to announce to all their physician friends the birth of a new product—Capsules Folia-Digitalis

Like the other members of the Digitalis family of Upsher Smith, this new product is produced at Foxglove Farm by the shores of Lake Minnetonka, where every single step right from the planting of the seed to the finished product is under the direct supervision of Dr Upsher Smith and his sons

It is here that careful work, rigid control, strict standardization are carried out, which have resulted in a Digitalis that is accepted by many authorities as the standard for comparison

Each batch of Upsher Smith's Digitalis is standardized by the Hatcher Cat Unit Method and, for convenience of calculation, each preparation carries a dosage equivalent, thus

(Upsher Smith), ½ grain

Each capsule represents ½ cat unit, is equal to 5 minims of the Tincture Digitalis (Upsher Smith) and is 50% more potent than the average commercial leaf

We want you to test the product for yourself, by submitting it to clinical trial at our expense.

The coupon brings you a prescription package with our compliments See page III —*Adv*

THE PEDIATRICIAN'S FORMULA

The first suggestion for the preparation of Mead's Dextri-Maltose came from pediatricians Naturally their preference for this particular form of carbohydrate is back of its very conception Dextri-Maltose brings mothers with their babies back to your office, not only because of its clinical results but because it satisfies the mother that her baby is receiving individual attention—that it is getting "a formula"

From your viewpoint, this mother-psychology is all the more an important point of medical economics because there are no feeding directions or descriptive circulars in the packages of Dextri-Maltose It is truly the doctor's formula See page XI —*Adv*

IPRAL SQUIBB

Affects only the higher cerebral centers, therefore, gives refreshing sleep closely resembling the normal To the restless post-operative case, to the chronic insomniac, and even to the violently maniacal IPRAL SQUIBB brings the needed rest which may turn the tide in favor of the patient's recovery

Being quite soluble, Ipral is quickly absorbed and rapid in action

IPRAL SQUIBB is distributed in 1 oz bottles and in 2 gr tablets in bottles of 10,100 and 1,000 Write to the Professional Service Department for Literature See page VIII —*Adv*

McGOVERN'S GYMNASIUM, INC

More and more physicians are realizing the futility of leaving patients to their own resources when exercises are prescribed, and have learned that through individual attention at McGovern's, their instructions will be faithfully carried out.

A work-out will convince you of the superiority of the McGovern Method. Let us send you a guest card No obligations, of course See page XV—*Adv*

VITA GLASS

Vita glass has been subjected to numerous accelerated weathering tests by the U S Bureau of Standards, by Professor Stockbarger of the Massachusetts Institute of Technology, and by many other physicists These physical or quantitative tests, as well as biological experiments with rats and chickens, have established the fact that the solarization (weathering or seasoning) of Vita glass takes place quickly, and that after a few weeks' of actual use its transmission of ultra-violet light becomes constant

Vita glass is being marketed primarily as a health prophylaxis and not as a therapeutic agent, although it is now serving in the latter capacity in numerous well authenticated instances—particularly in the solaria of more than 20 hospitals in England and the United States —See page XIX —*Adv*

LACTO-DEXTRIN

In an investigation of over 2,000 patients suffering from constipation and intestinal toxemia, the head of the Battle Creek Sanitarium laboratory found that the normal acid-forming bacteria could be restored in a satisfactory and efficient manner by the persistent use of Lacto-Dextrin (Lactose 73%—Dextrin 25%)

The extent of the change depends upon the amount taken, the length of time it has been given and the degree to which the intestine has been crippled by disease

By exclusion of putrescent foods and the continuous use of Lacto-Dextrin in smaller quantities an aciduric flora may be maintained after it has once been established by Lacto-Dextrin feeding

In cases of obstinate constipation, quicker results may be obtained by the combined use of Lacto-Dextrin with Psyllia (plantago psyllium)—a plant seed which provides bulk and lubrication See page VII —*Adv*

LILLY LABORATORIES

STERILIZATION INDICATIONS AND LIMITATIONS

BY S J APPELBAUM, M D, ROCHESTER, N Y

IT is my purpose to treat the question of sterilization from two widely different view-points first, as a therapeutic procedure exclusively for the well being and safety of the patient, and second, as a procedure carried out primarily for the welfare and safety of society

The first group falls into two general divisions those in whom sterilization is indicated during pregnancy, and those in whom it is indicated at or near full term

The indication in the first place is an incurable progressive disease, such as advanced tuberculosis, interstitial nephritis or a decompensated cardiac condition Such patients are not only entitled to an interruption of their pregnancies, but to sterilization as well The procedure here as advocated by Williams and others is to evacuate the contents of the uterus by hysterotomy followed by tubal sterilization The anesthetic preferably should be local The induction of abortion by the vaginal route followed at a later time by tubal sterilization is too much of a strain and risk for this type of patients In the second group, in whom sterilization may be indicated at or near full term, the operation is associated with cesarean section There is considerable difference of opinion among operators as to the practise of sterilization in this group

Green[1] of Boston in a paper delivered at the 1903 meeting of the American Gynecological Association states that "If a woman comes to cesarean section and recovers, she and her husband, if she has one, should be informed of her condition, and of the prognosis and treatment in the event of future pregnancy if subsequent pregnancy takes place, the responsibility of treatment rests upon the obstetrician and surgeon, but the responsibility for the condition rests elsewhere." He is apparently opposed to sterilization at any time in uncomplicated sections even if desired by both husband and wife. He also apparently believes that sociological considerations should not influence our decision as to sterilization

In the discussion which followed Green's paper, Williams stated that he did not believe we ought ever to sterilize the patient in the first pregnancy, or the first cesarean section, unless indicated by some distinct pathological condition On the other hand, he did not believe that the obstetrician was justified in performing cesarean section after cesarean section on pauper patients without suggesting sterilization He believed that such patients should be sterilized after the second section Davis of Philadelphia stated that from the standpoint of sociology, the woman and her husband had a right to request that she be rendered sterile Their wishes should not be opposed

Williams[2] in a later paper stated that after the third cesarean section sterilization is definitely indicated and that he does not hesitate to suggest it He does not advise delivery of more than three live babies by cesarean section Dr Richard C Norris in discussing Williams' paper stated that in all cases where some chronic ailment makes it desirable to terminate pregnancy, sterilization should be done He also suggests sterilization after the second cesarean section In the last edition of his text Williams[3] says, "The opinion of those authorities who consider that sterilization should form an integral part of every cesarean section is certainly open to question If the patient is intelligent the decision should be left to her and her family, but at the same time the undesirability of a one-child marriage should be strongly urged, whereas, with the ignorant it is strongly incumbent upon the physician to do what he thinks is best under the circumstances "Personally," he says, "I am unwilling to sterilize any patient at the first operation, unless operative complications necessitate the removal of the uterus, or unless the patient comes from a district where proper operative help might not be available in a future pregnancy On the other hand if she is weak minded or diseased or is liable to become a public charge, the operation is justifiable In general, with pauper patients it is my practise to effect sterilization at the third cesarean section."

DeLee[4] also states that "if the first section is done for eclampsia, placenta previa, abruptio pla-

* Read before the Rochester Pathological Society April 18 1928.

centa, prolapse of the cord, faulty mechanism of labor, pelvic tumors, in the absence of other indications the woman should not be sterilized If the woman has a large family, the question is discussable, but if there is only one child, and that one weak or deformed, it is better not to sterilize her

"If the cesarean operation is done for contracted pelvis, I earnestly dissuade the patient from such a procedure at the first section, pointing out the fact of the safety of subsequent operations, the possibility of death of the only child and the unhappiness of a one-child family At the second cesarean," he says, "I willingly sterilize, if requested, although lately since the mortality has been so much reduced, I often suggest a third operation"

Swift[6] of Boston published a paper in which he gave the results of thirty-eight replies to a questionnaire addressed to fifty members of the American Gynecological Association as to when sterilization is indicated following cesarean section There was unanimous agreement that a patient should be sterilized when a cesarean section is done if a future pregnancy would gravely imperil the life of that patient Some of the questions were

"Assuming that a patient with an absolute pelvic indication requests a sterilization at her first cesarean section, should this request be granted?" Twenty-three replied no, eleven replied yes, four were uncertain

"Should one refuse to sterilize a woman following a second, third or fourth cesarean section, if asked to do so by the patient?" Fifteen replied no, fourteen replied yes, nine were doubtful

"Should one advise a patient having a cesarean section for a definite pelvic indication to be sterilized at her first, second or third cesarean section?" Twelve replied no, twenty-two replied yes—divides as follows—two at first, five at second, seven at second or third, seven at third and one at fourth

"In your opinion do repeated cesarean sections increase the risk to the mother?" Twenty-two replied yes, fourteen replied no, two were doubtful

"Should the economic factor influence the decision as well as the purely problematical physical factor of increased danger to mother?" Sixteen replied no, fourteen replied yes, eight were doubtful

Swift is unwilling to sterilize at the first cesarean section unless there are definite indications other than the possibility of another section He believes that the maximum number of sections should be four Holmes of Chicago in discussing Swift's paper takes a clear-cut position When a chronic progressive disease complicates the indications for cesarean section, he insists that sterilization be part of the operation Pregnancy in such patients is a serious menace to life "For pelvic deformity alone, a difficult situation faces us It has been my rule," he said, "never to obtrude the thought of sterilization on the woman or her husband If the couple ask for it in the second section, I plead for delay with the argument that one or both of the children may die—a desire later for another child cannot be realized If they insist, I believe that any operator is justified in following their dictates" Is it not perfectly proper for any normal couple to control the number of their children for economic or other reasons? Is it not the prerogative of any woman to decide whether to run the risk of another cesarean section? Holmes' answer is that the patient has that right, and with that opinion I am very much in agreement

The second group, in whom the operation is considered solely from the point of view of the welfare and security of society, is a large one. It includes the mental defective, the habitual criminal, the degenerate, and others of like type.

Our national government recognized the present and potential danger of this group of individuals in framing our immigration laws The mental defective, the criminal, the epileptic, the insane and the degenerate are denied admission to our land, but the dweller *within* our land still presents a problem We either do not see the solution, or we shirk its application Sterilization of course is not a 100 per cent solution, but nevertheless it is an attempt to clean up the pollution at the head waters of the stream

The Council on Health and Public Instruction of the American Medical Association some years back issued a pamphlet opposing sterilization in this group and urging segregation as the proper measure Ochsner[9] in his presidential address befor the American Surgical Association in 1925, advocated sterilization of habitual criminals, imbeciles, perverts, paupers, morons, epileptics and degenerates Prof Jennings[7] of the Biological Department of Johns Hopkins University in an address last year before the National Tuberculosis Association suggested the desirability of checking reproduction, not only in the degenerate, but also in those physically unfit as a result of inherited tendencies These individuals have their diseased condition, he argues, because of genetic defects, and these have been passed on to their descendants These defects, inherited in the germ cells are largely responsible for cancer, tuberculosis, diabetes and diseases associated with glandular deficiencies Prof Jennings believes that some method of detecting genetic defects will eventually be found, and that race progress will be assured, if such persons can have no descendants to inherit their defects I question whether the human race will ever accept such biological standards However the idea is not new Socrates[8] was a strong advocate of eugenics as set forth in Plato's Republic

In 1865 Gregore Mendel, an Austrian monk,

read a paper on his experiments with peas of various types, tall, dwarf, smooth, wrinkled, yellow and green This work laid the foundation for our laws of heredity His experiments were repeated with animals and have found confirmation Morgan of Columbia, Jennings of Johns Hopkins, Wilson of Columbia, Castle of Harvard and their respective groups of associated students have done notable work in this field

The records of several well-known families are always referred to in any study of eugenics Dr Henry H Goddard, a former Superintendent of the School for Feeble-minded at Vineland, New Jersey, made a study of the Kallikak family Martin Kallikak, a young Revolutionary soldier of good family, mated illegitimately with a feeble-minded girl Among four hundred and eighty descendants from this union are one hundred and forty-three known feeble-minded, thirty-six illegitimates, thirty-three sexually immoral, eight keepers of brothals and eighty-three so feeble that they died in infancy About one hundred and fifty years later, one of the descendants was still an inmate of Vineland Later in life, Kallikak married a young Quaker girl of good talents and ancestry Their four hundred and ninety-six descendants are a line of fine people, soldiers, doctors, lawyers, judges, educators, men of big business—a group which has been a credit to itself and to the communities wherein they lived

The Juke family was last studied, I believe, by Dr Arthur Estabrook of the Carnegie Institute who brought the record down to 1915 Max Juke was a lazy, shiftless New England vagabond, born about two hundred years ago He finally settled in New York State His two sons married two sisters both mentally defective About twelve hundred and twenty descendants have been reported, three hundred of whom died in infancy, three hundred and ten were professional paupers, four hundred and forty were wrecked by disease, fifty were prostitutes, sixty were thieves, seven were murderers and fifty-three criminals of other kinds

Prof A E Winship of Boston, and Dr Davenport, have given us the history of the Edwards family Richard Edwards, a great lawyer, in 1677 married Elizabeth Tuthill, a remarkable young woman Among thirteen hundred and ninety-four descendants there are twelve college presidents, two hundred and sixty-five college graduates, sixty-five college professors, sixty physicians, one hundred clergymen, seventy-five army officers, sixty prominent authors one hundred lawyers, thirty judges, eighty public officials—state governors, city mayors and state officials—three congressmen, two United States Senators and one Vice-president of the United States In 1691 Edwards divorced his brilliant wife on account of immorality Later in life he married Mary Talcott, an ordinary, commonplace woman The descendants of this woman did not distinguish themselves in any way

Many similar studies have been made by Dr Davenport of Carnegie Institute and by Prof Anderson of Lexington Again and again in the literature the conclusion is drawn that no normal offspring results from the union of two mental defectives In the County Hospital you will usually find from one to three mentally defective babies delivered from one defective parent Dr R. A Gibbons[9] in the *British Medical Journal* suggests that, before a marriage certificate is granted to mental defectives, either or both be sterilized

Society can protect itself from this increasing menace to defectives either by segregation or sterilization Anticipating his annual report Comptroller Tremaine[10] of New York State makes the following statement "The number of inmates in State Institutions on June 30th last (1927) was 64,114 compared with 61,880 on June 30, 1926 an increase for the year of 2,234 The comparison for the five years shows an increase in that period of 7,920 inmates, a yearly average of 1,980

"It is clear, therefore, that the yearly increase in the number of wards of the State of New York is so great that, theoretically at least, the building of the hospital the size of the Rochester State Hospital, or the building of a penal institution of the size of Sing Sing every twelve months will probably be necessary to accommodate the additions to the population of state institutions"

Ochsner[6] makes the statement that in 1922 $162,459,000 was spent in the maintenance of state wards throughout the country—by far a larger amount than is spent for all the universities of the country This shows some of the implications of segregation as a solution of the problem

To January 1, 1926, twenty-three states[11] of the Union have passed laws authorizing sterilization for certain conditions under definite regulations In seven the statutes have been declared unconstitutional and in two of these new statutes have been passed In 1907 Indiana was the first state to enact such a law In 1912 New York State passed a law providing that under certain conditions procreation by feeble-minded, epileptic, criminal and other defective inmates of state institutions should be prevented, if the judgment was that their children would inherit a tendency to crime, insanity, feeble-mindedness, idiocy or imbecility, but in 1918 it was declared unconstitutional The criticism was that the statute had reference only to inmates of state institutions, and did no apply equally to all citizens of the state As a result of this court decision the state legislature in 1920 repealed the statute.

Ignorant of these legal technicalities and limitations, in 1924 and 1925 I performed three ster-

ilizations at the Rochester State Hospital in conjunction with cesarean sections In two of these cases there were definite obstetrical indications for the cesarean In the first case, seen in consultation with Dr C W Hennington, the indication was a placenta previa centralis in a primipara with a long, tight cervix She was feeble-minded, a dementia precox characterized by delusions of a paranoid type, mostly sexual She was operated upon on August 27, 1924 The indication in the second case was a generally contracted pelvis in a primipara, age 17 She had a history of an abortion at thirteen, two months in term Her sexual relations were very promiscuous Her hospital diagnosis was mental deficiency with psychosis Her mother was also definitely deficient She was operated on July 22, 1925 In the third case there was no obstetrical indication for the section She was a para three with a history of a normal first pregnancy and a mentally disturbed second pregnancy necessitating confinement in a state institution This was in 1921 Following delivery she improved and was discharged although she never entirely recovered mentally In 1925 she was admitted to the Rochester State Hospital again pregnant and after study she was diagnosed as a dementia precox She was operated upon June 12, 1925 All three patients made uneventful recoveries In each case the operation was approved by the staff of the State Hospital and written consent for the operation was obtained from the responsible relatives I am indebted to Dr Pierson of the State Hospital for abstracts of these cases There were several other patients in the hospital upon whom we were planning to operate These were mentally deficient and had been repeatedly admitted to the hospital because of pregnancy, usually illegitimate

Here let us briefly consider the several methods for effecting sterilization Sterility in the female may be produced by operations either on the uterus, tubes or ovaries, or by the employment of *x*-ray or radium In the male it may be produced by operations either on the testicle or vasa deferentia, or by the employment of *x*-ray or radium

The removal of the uterus should not be considered unless there is a definite lesion indicating its removal, apart from the question of sterilization

The first procedure to effect sterilization probably was ovarectomy, but with our present knowledge of the internal secretions of the ovary and the serious symptoms frequently associated with an artificial menopause, the operation should be performed only for seriously diseased organs The use of *x*-ray or radium is objectionable for the same reasons, as here again the functions of the ovary must be destroyed if sterility is to be produced, although with fewer distressing results than after removal

Operation on the Fallopian tubes is now the most usual method Lungren[12] of Toledo, Ohio, in 1880 was the first to attempt sterilization by tying both tubes with ligatures one inch from their uterine ends Following this, various operations on the tubes were devised, double ligation, double ligation with section, double ligation with excision of a small portion between the ligatures and crushing with ligation Nürnburger collected forty-two cases operated upon prior to 1897 In a paper on "The problem of effecting sterilization in association with the various obstetrical procedures" Williams[2] of Baltimore states that "In the forty-two cases two failures were noted The first being reported by Falaschi, who had ligated both tubes following a cesarean section without result, and as the patient soon afterwards became pregnant he was obliged to resort to a second section within a year Zweifel's failure was even more remarkable, as, in order to effect sterilization after a cesarean section, he doubly ligated both tubes and severed them between the ligatures The patient shortly afterwards became pregnant, and when he did a second section in 1894 he found that the cut ends of either tube had become reunited and that the ligatures had disappeared" Similar experiences had been reported elsewhere As a result of these failures operators resorted to salpingectomy and more recently to the wedge-shaped excision of the uterine end of the tube. Irving[13] of Boston has presented (whether or not it is original with him, I do not know) what I believe to be an improved method of tubal operation for the purpose of producing sterility He doubly ligates the tube about one and one-half inches from the uterine cornu and divides between the ligatures A small incision is then made on the anterior surface of the uterus just above the insertion of the round ligament merely going through the serosa. The proximal end of the tube is then buried in this pocket and sutured over and the distal end is buried between the leaves of the broad ligament I have used this method on three occasions and found it quite satisfactory

Sterilization of the male is comparatively simple Castration and the use of *x*-ray or radium have the same objection as ovarectomy or the use of rays has in the female Ligation and section of the vasa deferentia has been found entirely satisfactory

In June, 1925, the legality of my operations was questioned, and it was thought advisable to learn the exact legal status of the work we were doing I wrote to Dr C Haviland, Chairman of the State Hospital Commission, who passed the question on to the Attorney-General for an opinion This proved to be adverse, which of course made it impossible to continue the work

In May, 1927, the United States Supreme Court handed down a decision on the Virginia

sterilization statute which gave an entirely new aspect to the situation, however Justice Holmes in delivering his opinion said "In view of the general declarations of the legislature and specific findings of the Court obviously we cannot say as a matter of law that the grounds do not exist, and if they exist they justify the result We have seen more than once that the public welfare may call upon the best citizens for their lives It would be strange if it could not call upon those who already sap the strength of the State for these lesser sacrifices often not felt to be such by those concerned, in order to prevent our being swamped with incompetents It is better for all the world, if instead of waiting to execute degenerate offspring for crime, or to let them starve for their imbecility, society can prevent those who are manifestly unfit from continuing their kind

"But, it is said, however it might be if this reasoning were applied generally, it fails when it is confined to the small number who are in the institutions named and is not applied to the multitudes outside. It is the usual resort of constitutional arguments to point out shortcomings of this sort But the answer is that the law does all that is needed when it does all that it can, indicates a policy, applies it to all within the lines, and seeks to bring within the lines all similarly situated so far and so fast as its means allow Of course so far as the operations enable those who otherwise must be kept confined to be returned to the world, and thus open the asylum to others, the equality aimed at will be more nearly reached"

In this decision handed down by the Supreme Court of the United States, sterilization is held to be valid after taking into consideration the very same arguments upon which the highest court of New York State declared its statute to be unconstitutional The way is now open for the reenactment of the statute which the legislature repealed in 1920

We are living in an age of preventive medicine The impetus to other activities in this field—tuberculosis, diphtheria, cardiac disease—has come chiefly from the laity The medical profession, to its discredit, failed to take the initiative in these medical activities, and then found fault that they were being conducted by lay organizations without their cooperation or advice The medical profession, because of its technical knowledge of this medical-social problem, owes it to society at large to take the initiative, perhaps through its state society, in the solution of his problem

Conclusions

1 Sterilization during pregnancy is indicated in the presence of an incurable progressive disease, if the judgment is that the pregnancy should be interrupted

2 Sterilization is indicated at the first cesarean section, if a chronic progressive disease, such as would make future pregnancies dangerous, complicates the indication for the cesarean section

3 Sterilization is indicated possibly after the third and more certainly after the fourth cesarean section even if the indication for the section is not complicated by the presence of pathological conditions

4. Sterilization is indicated to prevent procreation by such as potentially would bring forth children with an inherited tendency to crime, insanity, feeble-mindedness, idiocy or imbecility

5 Sterilization in the female is best performed by double ligation, section and burial of the ends of the Fallopian tubes

6 Sterilization of the male is best performed by ligation and section of the vasa deferentia.

7 The question of sterilization with reference to the above group should be viewed as a problem in preventive medicine

8 Although New York State courts have declared its sterilization statute unconstitutional, the United States Supreme Court has declared a similar statute of Virginia to be constitutional

9 Sterilization as applied to defectives is a medical-social problem The medical profession through its State Society should take the leadership in the solution of this medical-social problem

SPINAL ANESTHESIA FOR ABDOMINAL OPERATIONS*

BY L F SISE, M D, BOSTON, MASS

From the Lahey Clinic, Boston, Mass

EACH year we have given at the Lahey Clinic a small number of spinal anesthesias Although we felt this anesthesia gave the very best possible operating conditions for abdominal surgery, yet, because of our fear of the vascular depression which accompanies it, for many years we used it only where other anesthetics seemed unsuitable Recently, however, improved methods and our greater familiarity with it have caused a gradual change in this attitude, and for the last year or more we have been using it as our anesthetic of choice with great satisfaction and increasing confidence

Advantages

One of the most striking advantages of spinal anesthesia is the intense muscular relaxation which it induces While this is of advantage in many operations, it is particularly useful in abdominal operations It is beyond anything obtainable in any other way Not even a deep ether anesthesia can equal it—and deep ether introduces toxic disturbances

The stomach and small intestine are in a state of tonic contraction Indeed, the pylorus may appear as if hypertrophied and might deceive a surgeon unprepared for this phenomenon The effect on the large intestine is variable Frequently is it contracted, though usually not as much as the small intestine

Respiration is shallow and quiet

This combination of extreme relaxation, contracted intestines, and quiet respiration makes exposure and manipulation easy Strong retraction and large tight packs become unnecessary The surgeon can work to a large extent unhampered, can work with accuracy, certainty, and speed, and is thus in a position to produce the very best surgery of which he is capable

Disadvantages

The disadvantages of spinal anesthesia are numerous, but for the most part they are unimportant or may be greatly lessened, and on the whole appear to be more than counterbalanced by its advantages

Vascular depression will be considered later, by itself

The fact that the patient is conscious, the effect of this on his mind, the necessity for a close operating room morale with the avoidance of careless remarks—all these are the same as with any other local or regional anesthesia The situation can be largely mitigated especially by preliminary medication If this fails, the patient may be definitely relieved by a light general anesthesia with gas This does little harm

The length of the anesthesia cannot be extended or shortened to fit unforeseen changes in the operation, and, in fact, is of limited extent in any event It is sufficient, however, to cover almost all operations Even where it does not cover the whole length of the operation, it will cover the more difficult and shocking part of it, and the balance can be pieced out with some other anesthetic

Failure to get anesthesia of sufficient height for the contemplated operation occasionally occurs With increasing experience and skill, failures decrease almost to the vanishing point. After a moderate amount of experience they should not run over one per cent or two per cent

Nausea and vomiting not infrequently occur during the operation This is unpleasant for the patient and interferes with the surgeon's work On account of the great relaxation of the abdominal walls, however, this interference is not as great as it is under other, less relaxing, forms of anesthesia If it persists it may be stopped by a light gas anesthesia

Morbidity

The morbidity of spinal anesthesia has lessened greatly as experience has been gained and as improvements in material and technic have been introduced

Headache has always been reputed to be the most common sequel Many of these are ordinary headaches due to the general nervous upset, especially in susceptible individuals Some, however, are directly attributable to the anesthesia. Of these there are said to be two types, the first due to leakage of fluid from the puncture hole, and characterized by low spinal fluid pressure and the fact that it is relieved by the Trendelenburg position, and the second due to irritation or infection, and characterized by high spinal fluid pressure and failure to get relief from the Trendelenburg position On the whole, headaches are no more disturbing than after general anesthesia

Paralyses may be due to trauma at the time of puncture or to irritation or infection from the anesthetic solution With proper technic these should be extremely rare They are practically always temporary

Much the same may be said of trophic disturbances and parathesias

Mortality

The most recent study of mortality is that by Rygh and Bessesen [1] These observers collected

*Read before the Section of Surgery, New York Academy of Medicine, February 7, 1929

[1] Rygh E A and Bessesen D H —Minn. Med. 11 744 747 (Nov 1928)

statistics on 250,895 spinal anesthesias, and found that the actual mortality in this series was 1 in 3,345 They then analyzed the deaths and found that a large proportion of them were due to manifest errors of judgment or technic. On eliminating such deaths they found the remaining mortality was 1 in 11,060

For the present, however, this figure of 1 in 11,000 is ideal, rather than actual or practical It must be borne in mind and emphasized that spinal anesthesia is surrounded by dangers and pitfalls, and that while there are efficient means for avoiding them, yet men who are ignorant of these means or who are inept in using them will probably record a high mortality

It is evident, therefore, that the mortality will vary very greatly with different men, that it will be very high with some and fairly low with others, and that the general average of reasonably good men will probably be somewhere around 1 in 3,000

Placing the Anesthesia

It is important in using spinal anesthesia that the anesthesia be placed at the desired height. It is important, also, that it be kept there during the operation, neither receding to cause the patient pain, nor progressing upward to cause annoying or dangerous symptoms

There are many different ways of placing the anesthesia at the desired height, and each way has merits of its own We have tried several of them, and have finally come to using gravity, because it appeared to us most logical and certain In addition, and of considerable importance is the fact that this method has inherent in itself the ability to increase the height of the anesthesia if the result of the first attempt at placement is not sufficiently high It does not appear that any other method contains this ability to change the height of the anesthesia after the injection of the anesthetic drug has been completed

To prevent the anesthesia from receding during the operation, a dose of the drug must be used which is sufficient to last out the operation It is impractical, however, to increase the dose and time beyond certain limits

To prevent the anesthesia from progressing upward during the operation, any excess of the solution remaining after anesthesia has been produced should be drained down into the lumbar region The use of a solution which is not readily diffusible also appears to be of advantage

The difference in the specific gravity of the anesthetic solution from that of the spinal fluid may be attained in two different ways The solution may be heavier than the spinal fluid, or it may be lighter than the spinal fluid

The heavy solution is much the easier to use. In my experience the anesthesia may be placed by means of a heavy solution with far more certainty and accuracy than by any other method This solution, however, has the rather serious drawback that, after its use, the patient cannot be put in more than slight Trendelenburg position without danger of its gravitating dangerously high (cephalad) in the spine This at once makes it unsuitable for all lower abdominal operations In addition it increases somewhat the danger of its use in upper abdominal work, since, in the event of marked vascular depression, a very useful treatment for that condition, namely, the assumption of the Trendelenburg position, becomes fraught with some danger It is because of this last fact that we have abandoned the use of heavy solutions in upper abdominal operations

A solution lighter than the spinal fluid is the one most generally useful in abdominal surgery A very good solution has been devised by Pitkin, is marketed under the name of "Spinocain," and is the one which we are now using for almost all of our anesthesias

The desired height of anesthesia may be secured with the solution in different ways Pitkin uses dilution with injection and re-injection several times Personally, we have relied on the lightness of the solution to float up in the spinal canal Either method may be used The important point is to be exact and painstaking

Vascular Depression

The greatest drawback to spinal anesthesia has always been the vascular depression which is so apt to occur with it The essential feature of this is a fall in blood pressure The pulse becomes small, the respiration depressed, the color pale and often a little cyanotic There may be thirst, air hunger, nausea, sweating, and prostrating weakness If the fall goes too far, unconsciousness and finally death may result. These are the phenomena of spinal anesthesia which in the past have made most men extremely cautious about using it

The chief cause of this vascular depression appears to be a vasomotor paralysis due to blocking of vasomotor fibres by the anesthesia In a very high anesthesia, slowing of the heart becomes a factor The respiratory depression which is usually in evidence probably tends to form a vicious circle with the vascular depression, each reacting unfavorably upon the other Lack of epinephrine caused by blocking of the splanchnics also may do its share in assisting the fall of pressure

In considering the treatment of the depression of spinal anesthesia, it is necessary to remember that this depression reverses itself as the anesthesia wears off and conductivity of the vasomotor fibres is re-established If the depression is not allowed to go too far, recovery is rapid and complete The fact that the cause of the depression is but temporary makes its treatment much more easy and effective than it would otherwise be All that is necessary, then, is to support the

patient for a comparatively short time, an hour or two, and he will be all right

The treatment of depression may be divided into three parts first, the prophylactic treatment, second, the treatment of slight or moderate depression, and third, the treatment of severe depression or collapse

Prophylactic treatment begins with the selection of the patient Very poor risks from any cause, such as old age, long illness, shock, hemorrhage, sepsis, etc, are poor subjects for spinal anesthesia Fortunately these weakened patients usually make good subjects for other, less relaxing, forms of anesthesia, such as abdominal field block and gas

It is important that the patient be well supplied with fluids Dehydrated patients are poor risks for spinal anesthesia All dehydrated patients and any others about whom there is the least doubt should be well supplied with fluids before attempting spinal anesthesia In most such cases, in order to be sure that they actually receive the fluid, it is well to give it intravenously or by hypodermoclysis The addition of glucose to the fluid is helpful It is also advantageous to time the last administration to come just before starting the spinal anesthesia, so that the vascular system will then be well filled with fluid At this time, for instance, there may be given 1500 c c of salt solution with 50 grams of glucose by hypodermoclysis A patient well filled with fluids will be much more resistant to a drop in pressure than one not so treated I should like to stress that, judging from our clinical experience, this appears to be quite an effective procedure.

The use of ephedrine just before starting the spinal anesthesia is a very efficient prophylactic measure Its use in this way has changed the whole aspect of spinal anesthesia Indeed, the recent introduction of ephedrine into spinal anesthesia is probably one of the important reasons for the present wave of popularity

This drug closely resembles epinephrine in its action It stimulates the sympathetic nervous system peripherally and thus brings back into play the very parts of the nervous regulating mechanism which are blocked out by the anesthesia It is thus a physiologic antidote It differs from epinephrine in that it stimulates the heart more, it is more effective when given subcutaneously, and its effect lasts very much longer A dose of 50 mgm will last one to two hours

While the primary action of ephedrine is to stimulate the heart, with increasing doses this effect is lessened and finally reversed. Large doses depress the heart and cause irregularities The dose of 50 mgm appears perfectly safe for all cases except possibly some of angina With care 100 mgm might be given in most cases It does not seem wise or necessary to exceed this amount.

Patients who have been selected with good judgment, who have ample fluid, and who have had a preliminary dose of ephedrine resist the tendency to a fall in blood pressure much better than those not so prepared, and respond more readily to treatment

If in spite of this preparation a drop in pressure takes place, it should be treated before it has gone very far When a drop in pressure starts, it is impossible to be sure whether it is to be a slight or a severe one If it is to be a severe one, the sooner treatment is started the better A severe drop in pressure so slows the circulation in the tissues that intravenous medication may be necessary for prompt results Early treatment of a slight drop in pressure becomes a prophylaxis against a greater one. It is thus a distinct factor of safety This I should like to emphasize, because it seems to me important, that the early institution of treatment, well before urgent symptoms arise, is a great measure of safety

Just the amount of drop in pressure which calls for treatment is debatable Personally I prefer to have the pressure a little below normal rather than above it because less energy is required of the patient On the other hand, patients appear to do better and there is less potential danger if an attempt is made to keep the pressure from dropping greatly We have taken two-thirds of the normal level, roughly, as the point above which we will try to keep the pressure

If there is a slight or moderate drop in blood pressure, a remedy which can usually be given more quickly than any other, and one which is at the same time quite effective, is to place the patient in Trendelenburg position This procedure has been thoroughly tried and tested by many different men and should be effective if resorted to quickly enough It gravitates blood to the vital nerve centers even though the vascular system is much relaxed Patients undergoing operations in this position are thus relatively safe, though great care must be used in levelling them after the operation. In upper abdominal operations this position is apt to be so inconvenient for the surgeon that we do not resort to it unless the condition is urgent

If it is not desired to use the Trendelenburg position, or if something more is needed, very good results are obtainable from the use of epinephrine This drug, like ephedrine, stimulates the sympathetic nervous system and thus brings back into play the very nerve forces whose blocking out by the anesthesia has caused the drop in pressure, and is thus also a physiologic antidote

The greatest difficulty in its use comes in getting just the right amount of effect. If too much is given too rapidly a violent rise of pressure will result, which will be quite distressing to the patient, which may put a considerable

strain on the vascular system and which may, if he is susceptible, throw him into auricular fibrillation. It is therefore well, except in emergency, to use small doses and proceed slowly It is better to use repeated doses than to get too great an effect from one.

Ephinephrine may be given intravenously, intramuscularly, or subcutaneously, the effect becoming slower and less marked with each procedure Its intravenous use is rarely necessary and would be only in collapse Unless the circulation has already become greatly slowed, an intramuscular injection will show its effect almost immediately Similarly the subcutaneous injection will take 2 to 10 minutes Both these times may be cut down and the effect increased by massage at the point of injection After the primary effect of the injection has subsided the effect may be repeated in a lesser degree simply by massage at the point of injection, and this effect may again be repeated similarly several times

Not over 0 5 c.c of the 1 to 1,000 solution should be used at one time for fear of an overaction. Half this amount is often enough A useful procedure is to give part of the dose subcutaneously and part intramuscularly The intramuscular part gives a quick reaction, and this is sustained and carried on by the less marked and slower action of the subcutaneous portion

If the patient is prepared for his anesthesia as described, and if moderate vascular depression is treated promptly, there is little reason to fear severe depression or collapse Collapse would be most apt to occur when the vascular depression of the anesthesia was complicated by marked loss of blood from the operation

If for any reason collapse does occur, the circulation in the tissues will then be too slow to take up the epinephrine with sufficient rapidity, and it must therefore be given intravenously A very useful procedure is to give a saline infusion and add epinephrine to it as needed to support the pressure In this way benefit is derived from the fluid added to the circulation as well as from the epinephrine. The infusion may be made by tapping a vein with a needle through the skin, but if the tap is unsuccessful, time must not be wasted in repeated trials, but the vein should be cut down on and definitely entered It the collapse is severe, speed is of paramount importance

Our Results

Up to January 1 of this year we have done 700 spinal anesthesias of all sorts with one death This patient was a man 73 years old, who had a high anesthesia for a stomach operation His death was due mainly to the fact that his serious condition was not appreciated sufficiently quickly Secondly, it was due to too slow efforts at resuscitation He was finally resuscitated, but not before cerebral degeneration had taken place, which caused his death two days later He therefore well illustrates the prime necessity of speed in such resuscitation. Thirdly, his death may have been due in part to the use of a heavy anesthetic solution and failure to use steep Trendelenburg position We feel that this death was distinctly avoidable, should not have occurred, and with our present experience would not now occur

During the year 1928, the first year in which we used any considerable number of spinal anesthesias, we performed under it 339 abdominal operations Of these, 137 were classed as upper abdominal, mainly gall bladder and stomach operations, and 202 were classed as lower There was one death, the one just mentioned. There was one case of respiratory difficulty sufficient to call for help from artificial respiration This patient at no time actually stopped breathing nor was he otherwise in a condition to cause any alarm In six cases the anesthesia was too low, in six cases it seemed unreasonably short, and in one case puncture was impossible Anesthesia was classed as unreasonably short if it failed to last an hour for an upper abdominal operation or an hour and a quarter for a lower These 13 cases may be classed as failures and amount to 3 8 per cent of these cases In contemplating this large percentage of failures, it must be remembered that we made several considerable changes in technic during the year Our percentage of error is considerably less at the present time In eleven cases, nitrous oxid was added to the spinal anesthesia solely because of the mental condition of the patient. In two cases it was added to control too frequent vomiting In four cases there was temporary mental disturbance for a few days after operation. These were all patients in serious condition either from old age or the nature of the operation In two cases there was severe postoperative headache. One of these patients moved decidedly while the needle was in the spine, probably tearing the dura The other was a neurotic individual whose headache did not appear till some time after she had left the hospital

Place in Anesthesia

Having taken this survey of the subject of spinal anesthesia, what may we conclude as to the place which it should occupy in the general field of anesthesia for abdominal operations?

That it greatly facilitates surgery there can be no doubt It gives the surgeon much better operative conditions than he can obtain in any other way While it facilitates all abdominal surgery, it does this especially in difficult cases, whether they are difficult because of the operation itself or because the patient is an unfavorable subject The quality of the surgery, therefore, should be better when done under spinal anesthesia than under any other anesthesia

In general, it may be said that anesthetics which give good relaxation, such as ether or chloroform, have much more toxic action on the body than those which give poor relaxation, such as gas or regional Spinal anesthesia is a striking exception to this general rule While it gives better relaxation than any other known anesthetic, it has little or no toxic action As a matter of fact, spinal anesthesia is simply a special form of regional anesthesia, and employs less of the anesthetic drug and shows less general toxic effect in proportion to the area of anesthesia than does any other form of regional anesthesia

There is only one aspect of spinal anesthesia which may keep it from leading all others as an anesthetic for abdominal operations This aspect is that of its safety Safety in an anesthetic is of paramount importance If an anesthetic is too dangerous it must be discarded, no matter how good it is in other ways

Let us, to simplify the matter, compare the danger of spinal anesthesia with that of ether Ether is selected for comparison because it has for years been the standard anesthetic, so to speak, and because it is the only other anesthetic, omitting chloroform as too dangerous, which gives relaxation and operating conditions which can compare with those under spinal anesthesia

The published statistics unquestionably show a higher mortality from spinal anesthesia than from ether Spinal anesthesia is surrounded by dangers and pitfalls, which, even though they can be avoided by the careful, will certainly trap the unwary, while ether, as far as immediate and direct mortality is concerned, is inherently safe and, to a considerable degree, "fool proof"

It is a question, however, whether the statistics as published give a fair comparison between the two anesthetics The deaths from spinal anesthesia are for the most part sudden, dramatic, and directly attributable to the anesthetic, and are therefore all credited to it It seems very probable that the deaths from ether are for the most part delayed, concealed, and attributed to something else Such deaths might be recorded as due to sepsis, obstruction, shock, pneumonia, uremia, etc It is impossible to go into this subject in detail here One illustration will suffice. From the Mayo Clinic, McGrath has reported 49,057 ether administrations with "no death ascribable to the anesthetic alone,"* and this has been taken to mean "no death in 49,000 cases"** From the same clinic, though not covering the same period of time, comes an extremely careful and convincing report by Lundy,*** showing delayed morbidity and mortality almost undoubtedly due to ether Six hundred ether administrations were followed by 21 deaths, for six of which Lundy felt ether was at least partly responsible. The incidence of pneumonia was more than twice as great under ether as under ethylene-ether and the mortality from pneumonia was over 60 per cent greater under ether Of course these exact figures cannot be applied to the whole 49,000 cases Yet these figures do suggest quite clearly that ether has a delayed and often concealed mortality which is not generally credited to it in compiling mortality statistics, but which in the ultimate analysis really does belong to it

In this connection it is pertinent to remember two facts In the first place, spinal anesthesia greatly facilitates abdominal surgery In the second place, the surgical mortality is always so much higher than the anesthetic mortality that a slight reduction in the surgical mortality will greatly outweigh anything but a marked increase in the anesthetic mortality

On the whole, it seems fair to conclude that spinal anesthesia is an anesthesia of such great potential danger that it is unsuitable for miscellaneous use, but that it so greatly facilitates surgery and it may be so effectively safeguarded that in the hands of careful and experienced men it becomes the anesthesia of choice for abdominal operations

SPONTANEOUS HEMATOMA OF ABDOMINAL WALL—CASE REPORT

BY HENRY N KENWELL, M D, BUFFALO, N Y

SINCE Culbertson[1] summarized the literature on forty-one case reports of spontaneous hematoma of the abdominal wall before the American Gynecological Society in 1925, the clinical observations in this condition have become more accurate and the condition recognized so that fourteen additional cases have been reported in the last three years This condition is hardly mentioned in our best text books, although it appears to be a definite clinical entity as pointed out by Weitz[2] and others Therefore, I am relating this case and adding it to the small group of twelve cases of spontaneous hematoma of the abdominal wall occurring in the pregnant state or in the puerperium

Definition—Spontaneous hematoma of the abdominal wall is the condition in which a more or less sudden painful swelling develops in the abdominal wall in one or more quandrants from a rupture of the internal mammary or deep epigastric vessels, generally in a woman past forty who gives a history of some previous infection or a pregnancy The more

common rupture of healthy abdominal muscles from external trauma with resulting small collections of blood is not considered in the group of so-called spontaneous hematoma of the abdominal wall

Etiology—Concerning the etiology, there is no universal agreement. Block[3] says hematoma is a misnomer inasmuch as it is only a symptom and not a disease, but that we must stick to it as long as the real cause is unknown and perhaps there are many causes for it Giuliani[4] discusses very completely the theories on the etiology of hematoma from rupture of the recti abdominal muscle fibers and cites several cases in which there seems no doubt that it was not from a ruptured large vessel He also reports cases where deep epigastric vessels were ruptured causing the hematoma.

Emerson[5] operating for a hernia found the deep epigastric artery and vein ruptured and could easily demonstrate the artery lying on the peritoneum It was severed about midway between Pouparts ligament and its entrance into the lower portion of the rectus sheath Active bleeding had stopped but he tied both ends

Weitz reports two cases of spontaneous hematoma of the abdominal wall and concludes in both cases that he was dealing with a spontaneous rupture of the superior as well as the inferior epigastric artery without participation of the rectus muscle itself in the causation of the hematoma After reading the cases reported of spontaneous hematoma of the abdominal wall, I do not doubt that they occur as the result of a rupture of the deep epigastric vessels and also from a rupture of the recti abdominal muscle fibers, but not as frequently as from the rupture of the vessels At least the clinical picture is different.

Concerning some of the predisposing causes, age seems to be a factor in that it occurs generally after forty

A varix from the deep epigastric vein would be much more liable to spontaneous rupture than the thicker walled artery would be, especially in the pregnant state when the circulation is increased Previous infections such as bronchitis or influenza have been noted in many of the reported cases Constant prolonged coughing causing repeated strain on the abdominal wall, also has been noted in several cases In Stoeckels[6], two cases of hemorrhage were occasioned by coughing but were not yet delivered

Vogts'[7] patient developed a bilateral hematoma following a precipitate delivery and was ascribed to the labor Arteriosclerosis was present in one case but is not an outstanding factor in the rest of the reported cases

Excessive, prolonged or sudden muscular strain of the abdominal muscle plays an important part in the production of these spontaneous hematomas

Symptomatology—These patients complain of a development of a painful mass in the abdomen which appears rather suddenly The mass is hard and upon palpation seems to be in the abdominal wall Echymosis may occur in the skin, especially around the umbilicus The patient ordinarily has an upper respiratory infection or bronchitis or influenza associated with a cough Pain due to peritonal irritation is commonly present Vomiting may occur

Diagnosis—The appearance of a mass in the abdominal wall conforming to the distribution of the deep epigastric or the internal mammary vessels, which is of rather sudden onset in a woman, who gives history of previous infection with a cough or in a woman recently delivered, is pathognomic of spontaneous hematoma of the abdominal wall

Differential Diagnosis—The history of sudden pain and a mass in the abdominal wall especially when accompanied by vomiting has caused many different intra-abdominal lesions to be diagnosed, generally depending upon the site of the mass

Some of the diagnoses made were

(1) Intestinal obstruction
(2) Ectopic pregnancy
(3) Acute appendicitis
(4) Pelvic tumor with twisted pedicle
(5) Ovarian tumor
(6) Incarcerated hernia
(7) Cholecystitis
(8) Strangulated Para-Umbilical Hernia
(9) Mesenteric Embolus

If the hematoma is very large aspiration may be done for diagnostic purpose Many of these hematomas become infected and later have fascial involvement in the suppurative process

Prognosis—The prognosis is good and there are relatively few complications Hernia is a possible sequel

Treatment—Small hematomas, no doubt, are best treated non-surgically, but large hematomas, it would appear, are better evacuated and drained before they become infected as suggested by Fothergill[8]

The case I wish to report is that of a woman age 37, who was admitted to the Gynecological Service of the Buffalo City Hospital on February 14th, 1928, complaining of a painful mass in the left side of her abdomen She had a precipitate labor with birth of a full term baby in her home on February 3, 1928, without the attention of a physician For three weeks previous to the delivery she had a persistent cough with chills, fever and generalized aches all over her body She said her abdomen was sore from constant coughing Her pains

were severe and close together, being present only for one hour before delivery It was her tenth pregnancy Seven of her children, including the above mentioned baby, are alive and well and two are dead All her labors and puerperiums were normal except for a phlebitis in her right leg after her second confinement She had one miscarriage three years ago

On her fourth post-partum day she felt a dull constant pain in the left upper abdomen Simultaneous with the pain was the appearance of a mass in the left side of the abdominal wall, which increased in size quite rapidly and did not subside

Her functional and past history did not reveal anything of importance except that during her pregnancies she has had varicosities in her right leg

Physical Examination—Examination showed the patient to be a rather thin, white woman who appeared exhausted She had a temperature of 100° F, a pulse of 110 and normal respirations Her tongue was coated There were slight dental caries Her tonsils were moderate in size and showed no evidence of infection She had a deviated nasal septum with some post-nasal drainage Ears and sinuses were normal Neck was normal Heart and lungs showed nothing abnormal Breasts normal

On inspection of the abdomen, a large mass could be seen in the left abdominal quadrant On palpation it seemed to be in the abdominal wall and extended from the left costal margin to the pubis and from the midline to the lateral abdominal wall It felt firm and was not especially tender Although the mass was close to the palpating hand, it gave the impression of being fixed to the layers below Around the umbilicus was an area of ecchymosis

Pelvic examination showed a normal amount of post-partum flow with concomittant associated involution of the uterus, which was pushed to the right and somewhat retro-displaced Rectal examination showed first degree internal hemorrhoids The veins of the right leg especially showed moderate varicosities

Laboratory Findings—Catherized specimens of urine showed many pus cells and a trace of albumen on several tests Her blood urea was 13 3 mg and blood sugar 133 mg per 100 cc blood Her blood pressure was 106 systolic and 50 diastolic Hemoglobin was 60% Sahli, Reds 3,350,000, Whites 11,550 Blood smear showed normal red cells and differential white count of 71%, polys, 3% L Monos, 2% L Lmy, 22% S Lym, and 2% Trans Wassermann and Kahn were negative Four Sputa negative for T B Bleeding time 2 minutes Clotting time 5½ minutes

Upon cystoscopy there was a bulging into the fundus portion of the bladder wall evidently caused by a mass pressing on the outside of the bladder in this region The ureteral orifices were displaced laterally more than normal There was no evidence of any marked cystitis and nothing otherwise unusual There was no ureteral obstruction Bladder specimen showed 100-200 leucocytes per h p f and 3-5 red cells per h p f Slight trace albumen. Spec Grav 1 014 Staining—neg T B—gram stain showed many gram negative bacilli Cultures showed many colonies of B Coli communis, scattered colonies of diphtheroids, a few colonies of staphylococcus aures and scattered colonies of B lactic aerogenes

Staining and cultures from both the right and left kidney showed the same organisms intravenous (30 min) P S P test showed right kidney—10 cc—18½%, left kidney—30 cc—45%, Transvesicle leakage 640 cc 20% Plain X-ray, pyelograms nad uretergrams were negative X-ray of Thorax was negative except for a moderate bilateral fibrosis No evidence of tuberculosis

The case was considered to be one of spontaneous hematoma of the abdominal wall from the rupture of the deep epigastric or internal mammary vessels

The abdomen was shaved over the mass and under aseptic precautions an aspiration was done About 50 cc of hemorrhagic fluid was removed Upon examination this showed in addition to the red cells, also pus cells with hemolysis of many of the red cells Direct smears showed many staphylococcus Fresh smears showed many hematoidin crystals and red blood cells Negative for T B Cultures showed many colonies of staphylococcus aureas hemolyticus

Thus we felt that inasmuch as the hematoma had become infected it was best to open and drain Under nitrous oxide-oxygen anaesthesia an incision was made over the left rectus muscle in its upper portion Upon opening through the skin and the anterior sheath of the rectus a large fluctuant mass was found, which was opened and about 750 cc of blood clot and hemorrhagic purulent material evacuated Upon exploration of the cavity it was found to extend from the costal margin to the pubis and from the midline to the lateral abdominal wall The wall was very pliable and the only thing that separated the intestine from this cavity was a somewhat thickened layer of peritoneum The hand could easily palpate the loops of intestine. The hematoma was apparently from a rupture of the branches of the internal mammary or deep epigastric

vessels and was in between the peritoneum and the posterior part of the left rectus muscle It had become secondarily infected Their was considerable bleeding which was controlled by pressure The cavity was drained with oil silk and closed loosely with silk worn sutures

It drained for about fifteen days and the patient went home on her twenty-third post operative day with a fairly strong abdominal wall and with no evidence of any hernia

Comments—The following points were considered of enough interest to report this case and add it to the small group of cases of spontaneous hematomas of the abdominal wall occurring in the pregnant state or in the puerperium

(1) It is evident that we were dealing with a spontaneous hematoma of the abdominal wall similar in many details to previously reported cases

(2) This case was diagnosed by several clinicians as a spontaneous hematoma of the abdominal wall most probably from rupture of a deep epigastric vessel

(3) It is also logical to assume that the previous violent coughing and infection, influenza, bronchitis and pylenoephritis and the precipitate labor with its trauma on the deep epigastric vessels played an important part in the etiology of this case I also wish to call attention to the anatomical relation of the deep epigastric vessels to the round ligament of the uterus which in a spontaneous delivery could well add to the trauma of these vessels It is of interest to note that her veins showed varicosities in her legs

(4) One of the helpful diagnostic signs was an ecchymosis around the umbilicus

(5) This condition was not an abscess with secondary hemorrhage because of the sudden appearance of the mass which gradually increased in size and conformed to the distribution of the deep epigastric vessels Also, it is well known that hematomas become secondarily infected

(6) Early drainage of this large hematoma before infection had taken place would have prevented the extensive destruction of the muscle and fascia and would remove the possibility of peritonitis from rupture of the infected material into the peritoneal cavity

EFFECT OF ADMINISTRATION OF LUGOL'S SOLUTION ON TWELVE CONSECUTIVE CASES OF EXOPHTHALMIC GOITER

By GEORGE M. GOODWIN, M D, NEW YORK, N Y

From the Thyroid Clinic of the Medical Department of St. Luke s Hospital.

A GRAPHIC illustration of the effects of Lugol's solution on the metabolic rate of twelve consecutive cases of exophthalmic goiter is given in the accompanying chart H S Plummer[1] began the use of Lugol's solution in exophthalmic goiter in 1922 and soon became impressed with the beneficial effect of this therapy He developed a routine involving the administration of ten minims of Lugol's solution three times a day for about ten days by which time there was marked improvement in symptoms and reduction in basal metabolic rate Resection of the gland was then performed and Lugol's solution continued in the same dosage throughout the period of postoperative reaction After this ten minims were given daily to the patient for eight weeks This routine resulted in a decrease in the severity of operative reactions and in a reduction of the operative mortality from 3 5 to approximately 1%

The manner in which iodine produces an amelioration in the symptoms of cases of hyperthyroidism is a matter of hypothesis Starting with the premise that there is a clinical difference in the toxaemia caused by a hyperplastic and that caused by an adenomatous goiter Plummer suggested that in adenomatous goiter the toxaemia was due to an excess of normal product while that of the hyperplastic goiter was due to an excess of abnormal product Many investigators have gained the impression that the symptoms of the toxaemia of the adenomatous goiter were milder and the reaction to operation less severe than in the toxaemia of the hyperplastic goiter Accord-

ing to the two-product theory the toxaemia of the adenomatous goiter is due to an excess of normal secretion, the toxaemia of the hyperplastic goiter is due to an excess of abnormal product This product is abnormal in that it lacks iodine, and, when iodine is administered to these cases the product becomes normal Under the latter circumstances the symptoms become milder and resemble those of the case of toxic adenomatous goiter The two-product theory has not met with general acceptance In fact there are many who refuse to make either a pathological or clinical distinction between adenomatous and hyperplastic types The role of iodine in the body chemistry is still obscure and it is quite possible that the thyroid is only one of the tissues or organs whose function and structure are influenced by faulty iodine metabolism The sedative effect of iodine upon the nervous factor as well as the metabolic factor of the exophthalmic syndrome may indicate that it affects the nervous tissues directly and not indirectly through the agency of the thyroid

The administration of iodine in Lugol's solution has been generally adopted in the treatment of thyroid toxaemia There has been expressed in the literature a great deal of difference of opinion as to the wisdom of using iodine except in the preparation of cases for operation The preponderance of opinion seems opposed to its use except in those cases in which operation is contemplated and in cases which have been operated to prevent regeneration of the thyroid Our own experience has been limited chiefly to the preparation of cases for operation and the treatment of recurrence of symptoms afterwards altho a few cases have come under our observation treated with Lugol's solution continuously over a long period without operation In these we have not seen the eventual exaggeration of symptoms described by others

Graphs of the metabolic rate in twelve cases of exophthalmic goiter coming under observation consecutively are given here because they show strikingly the effects of Lugol's solution All of these cases were of the exophthalmic or hyperplastic type of goiter and the hyperplasia was demonstrated microscopically after operation in all cases except No 12 which did not come to operation None of the cases were pathologically of the adenomatous type.

In all of the cases the observations were made while the patients were resident in the hospital and at rest in bed In ten of the cases the metabolic rate was estimated upon admission and again after a period of bed rest without Lugol's solution, they were then given ten minims of Lugol's solution three times a day for a period and their basal metabolic rate estimated again In the graphs the period of rest in bed without Lugol's is represented by a continuous line while the period during which Lugol's was given is represented by the broken line

In cases 1 to 7 the metabolic rate was estimated after a ten day period of rest and again after ten days of Lugol's solution with the following results

Case	Admission	After 10 days of rest alone	After 10 days with Lugol's
1	+56	+56	+42
2	+43	+47	+27
3	+65	+67	+41
4	+62	+56	+31
5	+82	+88	+45
6	+53	+43	+31
7	+56	+45	+42

The graphs of the first five cases distinguish very clearly the difference in the effects of the rest alone and of rest and Lugol's solution on the metabolic rate In case 6, the descent in the rate was about the same in each period In case 7, greater reduction occurred in the first period than in the second altho further reduction occurred when Lugol's was continued for ten days longer

In order to establish whether the metabolic rate might not drop in the second ten day period even if Lugol's was withheld cases 8 and 10 were given twenty days of bed rest and then the ten days of Lugol's solution In case 8 the rate was unchanged after twenty days (+51) but after ten days of Lugol's dropped to +30 In case 10 the rate dropped after the first ten days from 63 to 49 and then rose after the second ten days to 126 The last result was surprising for while the patient seemed more nervous and uncomfortable than she had been the increase in rate seemed out of proportion to the increase in symptoms The rate was estimated again therefore the following day when the same rate was obtained Lugol's was then started and in ten days the rate had fallen to +13 Case 12 was treated with rest without Lugol's for 51 days During this time there was little change in her symptomatology and the metabolic rate remained above +40 Ten days after Lugol's was started the rate had fallen to +30

Case 9 was given Lugol's without a previous period of bed rest and the rate had fallen in ten days from +40 to +20 This would indicate that the previous period of rest in the preceding cases had no influence on the effect of the administration of iodine

In case 11 estimations of basal metabolic rate were made at frequent intervals Plummer has stated that the basal metabolic rate is apt to fall precipitously on the sixth or seventh day following the beginning of iodine therapy Unfortunately we were unable to obtain the rate in this case on these days She was placed on Lugol's solution immediately on admission and the rate which was +96 on the first day had fallen to +50 by the seventh day By the sixteenth day the metabolism had fallen to +38 and remained at this level on the 18th and 20th day By the 30th day it had risen to +49 The Lugol's was then stopped and in seven days the rate rose to +70

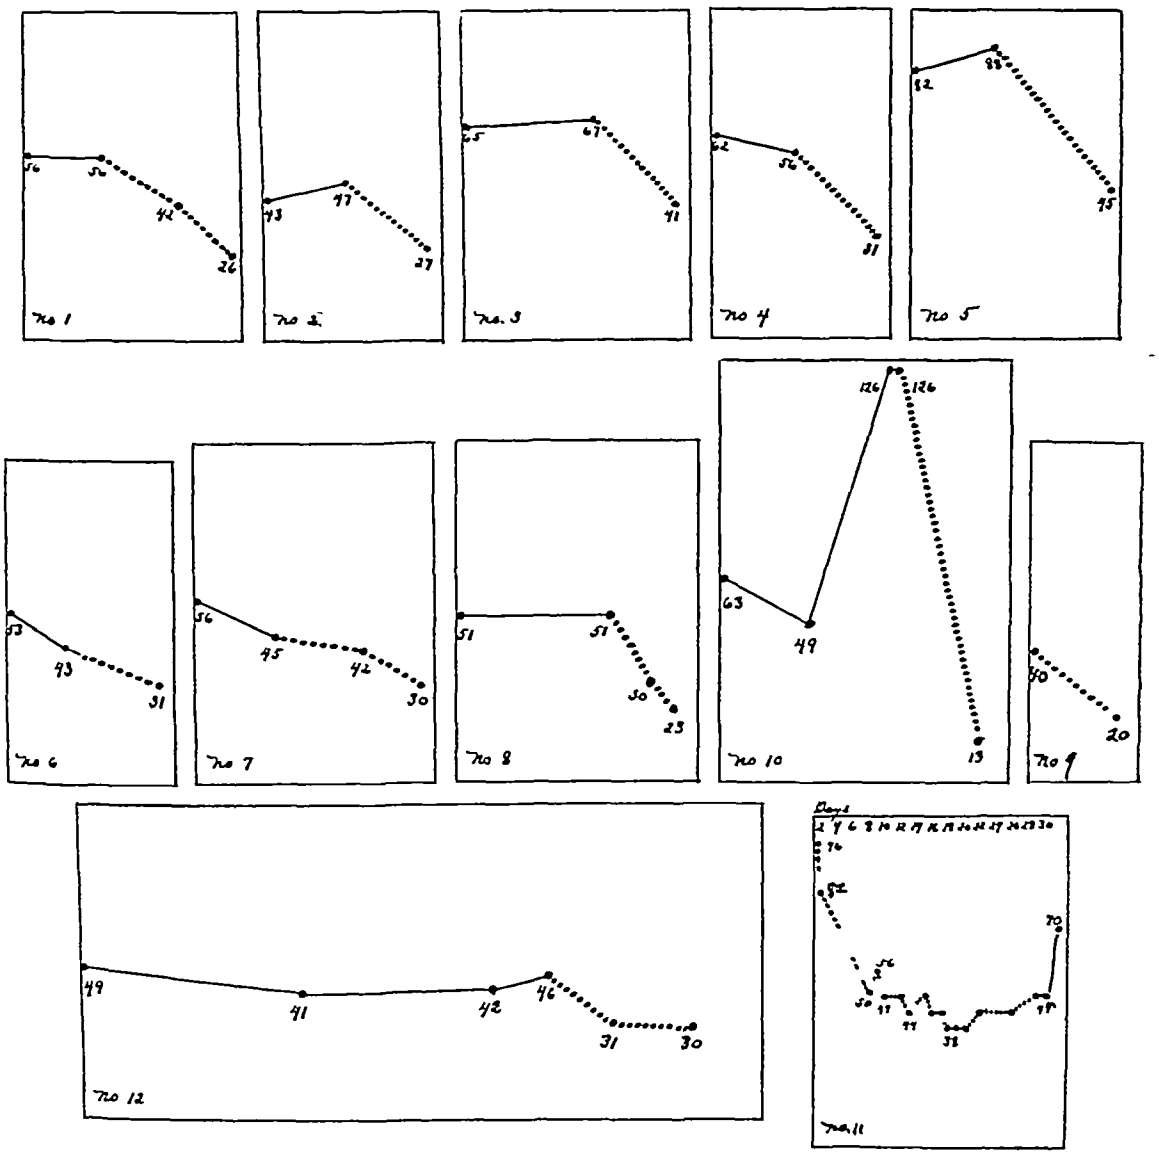

Chart Showing Effect of Administration of Lugol's Solution

Lugol's was then given for seven days and the rate fell again to +49

Conclusion

The effects of the administration of Lugol's solution (compound solution of iodine) upon the metabolic rate in twelve cases of exophthalmic goiter is convincingly demonstrated in this report These cases had never previously taken iodine The cases are not sufficient in number to draw conclusions as to whether the metabolic rate is so affected in all cases

THE REDUCING DIET*

By ARTHUR H TERRY, JR, M D, NEW YORK, N Y

IN order to lose weight it is necessary to eat less than is burned in the body Therefore, if it is known how much the body burns, it is not difficult to know what to do about it Either eat less or burn more How much to eat to maintain body equilibrium has already been determined for us

The ordinary man or woman at rest, weighing 150 pounds burns about 10 calories per pound or 1500 calories At work more is required in proportion to the amount of work done A diet containing 1500 calories for the active person is consequently a reducing diet and a diet of less than 1500 calories is more reducing

Some people burn more than others according to their activity and their metabolism and also from the nature of the individual Why one person stays fat and another lean is a question, but there is no doubt about the fact that an undernutrition diet will cause a loss of weight, words from the stout fellows to the contrary not withstanding And so if the calories are down, down goes the weight If a person weighs under 150 pounds he may be given proportionately less food, but by and large the same diet seems to fill the bill for the average person The amount being determined, the kind of food may be noted

Kinds of Food—Foods consist of three sorts Fats, carbohydrates and proteins but the greatest of these is proteins They are the essential muscle restorers and are not replaced except in part by the carbohydrates or fats A reducing diet, therefore, needs an adequate amount of proteins How much it is easy to calculate The 150 pound man weighs 70 kilos and a gram of protein is required for each kilo, more in children, but little less ever A reducing diet should contain 70 grams of protein at least and as a margin of safety half as much again, or about 100 grams These are found in fish, flesh and fowl and the milk or eggs therefrom

Carbohydrates—The second kind of food is the carbohydrate This constitutes the bulk of our normal diet, about four times the amount of protein or fat It is a good food and tasty and friendly to the burning of fat and so should be employed in dieting, especially as it provides much bulk, often with few calories A gram of carbohydrates has the same caloric value as the gram of protein, 4 calories, but the types of carbohydrates vary so in concentration that only the least concentrated should be used These, of course, are the 5 and 10 per cent vegetables and fruits They fill and tend to satisfy and so should be used as much or more than the proteins

Fats—Last but not least—the fats, a certain amount of which it is impossible to avoid as an egg contains as much fat as protein, meat nearly half as much, and cheese two-thirds as much. Fats sneak in every which way, mostly with their close allies the proteins, but frequently as plain butter, cream or olive oil The cook fires a tablespoonful at the string beans, and in the lettuce there is rarely a blade or leaf too mean to refuse the limpid 9 calories per gram of olive oil Whither we look or whither we listen, we find the olive oil *or see it glisten* Also, *be it remembered* that a 15 gram butter ball containing 135 calories slips down far more readily and with less gustatory satisfaction than its caloric equivalent such as one dish of oatmeal or 20 ounces of string beans Fat then has no proper place in the reducing diet except as a stowaway or unavoidable companion to better food It should be reduced to the minimum—in salad dressing replaced by mineral oil and as butter omitted entirely

Proper Diet—A proper reducing diet would, therefore, contain 70 to 100 grams of protein and 100 grams of carbohydrate, also it would have to contain about 50 grams of fat

How to offer this to the sufferer becomes the next problem Most people who diet do not choose to weigh their food and indeed it is not necessary, but a little knowledge is necessary so a brief resume of the foregoing should teach them to avoid especially butter and all other fats, eat proteins three times a day and take carbohydrates in diluted form as outlined in the diet A list of 5-10-15-20 per cent fruits and vegetables is provided, similar in form to that given on one of Dr Joslin's diabetic cards (See Table 2)

The Diet Detailed—A basic diet is outlined as follows to be modified to suit the situation

Breakfast Raw fruit 3%-10% list (average portion) Tea or coffee with 1 ounce of cream and 1 lump of sugar 2 boiled eggs

Lunch 3 ounces of meat fish fowl cheese or 1 glass of milk One 5% or 10% vegetable One 3%-10% fruit.

Dinner Clear soup Oysters or clams, if desired 3 ounces of meat, fish, fowl, cheese or 1 glass of milk. One 5% or 10% vegetable. One 15% or 20% vegetable. One 3-10% raw fruit.

This diet contains about carbohydrates 100, proteins 80, fats 50 calories 1200

Diet Discussion—This diet of 1200 calories allows for a margin of error—like two of the cook's butter balls, but it serves as a starting pattern so that one may add or subtract or substitute, but always in kind When the ideal weight is achieved, then enough is added to just maintain it Where eggs are disliked for breakfast, a slice of toast may be taken instead, but it is *not so* ideal in that it does not stay by a person *Better to give foods* that stick and even cause a *little indigestion* No same diet fits any two victims *but there are a few* general rules, and one of these is that proteins three times a day are essential

*Read before the Hospital Graduates Club October 25, 1928

TABLE I ANALYSIS OF 15 CASES, *SHOWING PROMINENT SYMPTOMS AND THE RESULTS OF TREATMENT*

Patient's number	Age	First weight	Second weight	First blood pressure	Second blood pressure	Interval	Loss of weight	Loss of blood pressure	Diagnosis	Result of treatment
58	65	182	170	220/125	210/120	18 months	12	10/5	Hypertension, apoplexy (old), nephritis, carious teeth	Patient improved
177	79	178	137	200/80	165/65	18 months	41	35/15	Albuminuric retinitis, hypertension	Patient improved Acute retinitis disappeared
195	55	126	119	175/100	175/100	7 months	7	0	Hypertrophied tonsils, hypertension	Unimproved
221	46	136	117	210/100	170/90	12 months	19	40/10	Paroxysmal tachycardia, hypertension	Improved Less frequent attacks
318	63	153	140	198/105	195/95	38 months	13	3/10	Hypertension, nephritis, hypertrophied tonsils	Improved
355	51	163	152	240/100	172/95	12 months	11	68/5	Hypertension, nephritis, albuminuric retinitis	Improved Acute retinitis disappeared
378	49	190	176	160/105	155/90	39 months	14	5/15	Obesity, hypertension	Improved
424	72	183	168	170/70	158/70	50 months	25	12/0	Obesity, hypertension, myocarditis	Improved
439	57	148	135	178/100	155/100	6 months	13	23/0	Hypertension, mitral stenosis, auricular fibrillation	Improved
630	70	170	155	190/60	165/70	36 months	15	25/+10	Hypertension, myocarditis	Improved
639	57	161	127	195/130	208/115	66 months	34	+13/15	Obesity, hypertension	Improved
645	71	198	190	186/100	190/90	26 months	8	+4/10	Hypertension	Improved
908	41	194	173	200/110	170/92	7 months	21	30/18	Hypertension	Much improved
801	70	135	130	190/95	160/85	1 month	5	30/10	Hypertension	Improved
796	57	155	144	190/100	165/90	5 months	14	25/10	Obesity, hypertension	Improved
Total	903	2472	2220	2902/1480	2613/1367	341 months	252	289/113		
Average	60	165	148	193/99	174/91	23 months	17	19/8½		

Special Diets—For the fat person who is reducing merely for his figure, the above diet is satisfactory but frequently associated with obesity are hypertension and nephritis In these two allied conditions, it is my impression that a glass of milk at noon associated with a salad and a few crackers, is preferable to meat, also where the nephritis is severe, milk or cheese at night may likewise be substituted for meat Meat has long had a bad name, and red meat especially, but of recent years it has found such favor that the roast beef of old England is flashed in the face of a nephritic with less modesty than mother's milk Tradition has its place in medicine and so I believe that meats of all kinds should bow to the simpler forms of dairy products A chicken's wing may be as poisonous as a steer's rump, but at least there is less on it and so it may be offered from time to time without much insult to a sclerotic pair of kidneys I have seen a person's countenance fairly radiate when told he might struggle with a chicken's wing Tuesdays and Thursdays instead of devoting his entire meal to milk and cheese and vegetables with a little fat to replace the diminished protein

Dangers of Dieting—The reducing diet, like any form of treatment, has its dangers—and they are not imaginery Some diets are worse than others, but all reducing diets are under-nutritional and unnatural It is true that a man can live on his belly for some time, and it may be true that, as is a lean mixture to a gas engine, so also is a slightly sustaining diet to a human being, but one of my patients developed tuberculosis while going along for two or three years keeping her weigh and blood pressure down Her pressure went down but her temperature went up and she died Another former patient developed tuberculosis while on quite a ridiculous diet A third came to me with an acute hyperthyroidism beginning shortly after the onset of dieting Such, then, are some of the disadvantages due to undernutrition Other pros and cons may be seen from a little study of fifteen patients who were placed on the reducing diet, all having high blood pressure, and kindred diseases Selection was made on the basis of having lost weight and having returned for observation The diet was varied to suit the individual, but no drugs employed (See Table 1)

TABLE 2—LIST OF 5, 10, 15, AND 20 PER CENT FRUITS AND VEGETABLES

5%	10%	15%	20%
lettuce	string beans (older)	green peas (older)	potatoes
cucumbers	pumpkin	parsnips	shell beans
spinach	turnip	lima beans (young)	baked beans
asparagus	squash	———	green corn
rhubarb	beets	raspberries	boiled rice
endive	carrots	currants	macaroni
sauerkraut	onions	apricots	———
dandelions	green peas (young)	pears	plums
beet greens	———	apples	bananas
celery	strawberries	blueberries	prunes
mushrooms	lemons	cherries	
tomatoes	cranberries		
sprouts	peaches		
cress	pineapple		
cauliflower	blackberries		
cabbage	oranges		
radishes			
string beans (young)			
broccoli			
———			
grapefruit			

GROUP RESULTS IN 15 CASES LISTED IN TABLE 1, ALL SHOWING HYPERTENSION

Average weight when first seen	165 pounds
Average weight when last seen	148 pounds
Average loss of weight	17 pounds
Average first systolic blood pressure	193
Average final systolic blood pressure	174
Average drop of systolic blood pressure	19
Average first diastolic blood pressure	99
Average final diastolic blood pressure	91
Average loss of diastolic blood pressure	8
Average time observed	23 months or 2 years
Average age	60 years

SUMMARY

A diet of 1500 calories is a reducing diet.

In this diet 50 grams of fat are unavoidable, 100 grams of carbohydrate advisable, 70-100 grams of protein essential

Special variations of diet are required to suit the individual case

Any undernutrition diet is dangerous

The reducing diet in hypertensive cases who are overweight will reduce the systolic pressure appreciably and the diastolic pressure slightly

SINO-AURICULAR BLOCK DUE TO DIGITALIS

By LOUIS FAUGERES BISHOP, M D, AND LOUIS FAUGERES BISHOP, JR, M D,
NEW YORK, N Y

THE true nature of sino-auricular block is as yet unknown, or at least there is no real agreement in regard to what the underlying mechanism is McKenzie was the first to call attention to this phenomenon as an accompaniment of influenza in 1902 Since then many cases have been reported in the literature Levine has called attention to the frequency of sino-auricular block after taking digitalis, and the following case report illustrates this

REPORT OF A CASE

E O, a physician, age 59, when first seen complained of weakness He had had all the minor diseases of childhood, including scarlet fever Several attacks of tonsillitis and occasional twinges of rheumatism Family history was irrelevant Six months previous to being seen he had had a severe throat infection and had not been well He complained of feeling

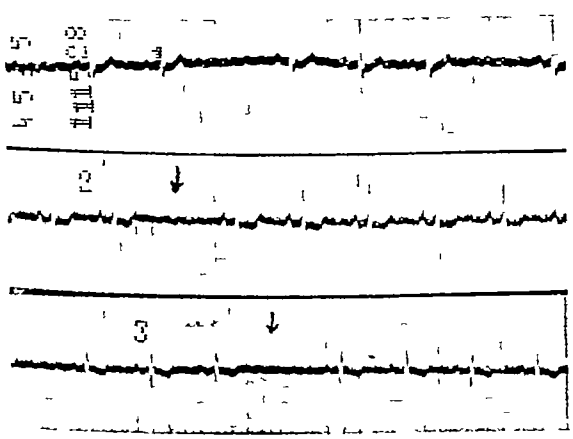

FIGURE 1

Electrocardiogram taken November 15 1928 leads 1 2 and 3 rate 70 illustrating the condition termed 'sino-auricular block' long cycle being approximately double the length of rhythmic cycles T wave inverted in leads 2 and 3 (Scale on abscissa is 0.2 second and on the ordinate is 10-4 volt)

extremely tired and had noticed slight dyspnœa on exertion He had been taking a grain of digitex every three hours for three days before being seen and previous to that had taken this three times a day for a month

Physical examination revealed a well developed and nourished man of middle age His tonsils were large and hypertrophied There was sclerosis of the retinal blood vessels No apparent enlargement of the heart and the apex beat was not seen or felt The heart rate was 70 and the rhythm was interrupted apparently by extrasystoles. Exercise did not affect or eliminate the arrhythmia except to increase slightly the rate There were no murmurs Systolic blood pressure was 110 and the diastolic 60 The remainder of his physical examination was entirely negative

Laboratory data revealed hæmoglobin of 82% Red blood cells 4,700,000, and white blood cells, 7 200 Differential blood count—

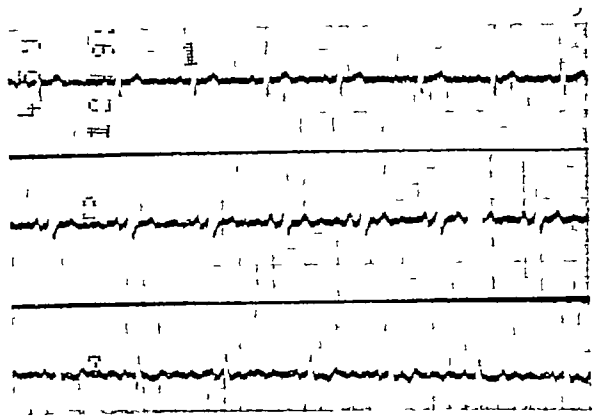

FIGURE 2

Electrocardiogram taken December 19, 1928, leads 1, 2 and 3 normal sinus rhythm rate 70 T wave upright in leads 2 and 3 (Scale on the abscissa is 0.2 second and on the ordinate is 10-4 volt)

lymphocytes 33 polynuclears 65 and eosinophiles 2 Urinalysis negative Wassermann negative

Roentgenogram of the heart showed moderate cardiac enlargement with slight tortuosity of the aorta The electrocardiogram was characteristic of sino-auricular block The pauses corresponded approximately to the length of two normal cardiac cycles An inverted T wave in leads II and III was also present

Treatment consisted in the withdrawal of digitalis and tonsillectomy One week later the sino-auricular block had entirely disappeared and was not obtainable on the electrocardiogram A month later the T wave had become upright and the rhythm apparently restored to normal

COMMENT

Although there is no great clinical importance to this phenomenon per se, the marked improvement following the withdrawal of digitalis both clinically and electrocardiographically is of unusual interest

PERSONALITY CHANGES IN DISEASE, WITH SPECIAL REFERENCE TO TUBERCULOSIS*

By LOUIS J BRAGMAN, M D, SYRACUSE, N Y

IT is a truism in medicine that the maximum service can be rendered a patient only when he is considered in the light of a sick individual rather than simply as a case George Eliot recognized this when she visualized the ideal physician as one who cared not only for cases, but for John and Elizabeth, too Admittedly a truism, how little is this element regarded in the everyday diagnosis and treatment of patients! The personality factor is generally neglected in favor of the more tangible and hence more interesting physical phase of the illness The mind which lies back of the disease is thus passed over, to receive consideration only when it overbalances and behaves in such an outspokingly peculiar fashion as to require the immediate services of a psychiatrist

Since everybody has a mind, so must there be found in almost every physical disease a mental component, an associative change which can be discerned chiefly in the field of the personality As stated by Casamajor, in an article called the Personality of the Patient, a Neglected Factor in Treatment, "there is an individual psychologic reaction to disease which plays an important part in the symptomatology, prognosis, and treatment of all diseases" This personality, as such, depends on many things, being determined largely by instinct, early experience and training, and the acquisition of certain mental habits, interests and attitudes

Paton says that the personality expresses the individual's biological capacity for adaptation, and in a certain sense measures the degree of adaptation of which he is capable at all the different levels of living, reflex, autonomic, and voluntary Just as individual personalities may vary, so may individual reactions to disease vary Considering, then, illness as a type of condition demanding adaptation, in what fashion does the mental state alter in response to disease?

At the start one must recognize a normal periodic ebb and flow in personality in states of health We are obviously not the same as far as mood, emotional reaction, attitude towards self and reality, sociability, and energy output are concerned, from one hour to another, from one day to the next, depending on varying prospects by way of altering environment or fluctuating fortune Such reactions are normal in the broadest sense, and are direct responses to normal shifting demands of everyday life

A somewhat similar normal response is to be found in the field of personality in disease One naturally expects with every ailment, and depending on the degree of nervous stability of the patient, a certain amount of apprehension, anxiety, and fear A sick person always represents a changed personality no less than a changed physique

More particularly there are alterations in the personality of a more specific nature, depending on the type of disease encountered That involvements of the nervous system should be accompanied by gross aberrations in the personality is to be presumed a priori The psychoses are the outstandingly great personality-provoking diseases, representing as they do pronounced physical and functional disturbances in that chief personality-controlling organ, the brain Without attempting to detail the wide range of symptoms met with in mental ailments, from the mildest sort of depression, for example, to advanced intellectual deterioration, it may be of value to mention one condition, namely, general paresis, in which early personality changes are practically pathognomonic An unprecedented shift in character and conduct from extreme orderliness in affairs to neglect and carelessness is in this instance invariably the first auspicious indication of an inevitable mental breakdown Somewhat similarly, one may discern that the arteriosclerotic brain case becomes irritable, irrascible, and explosive, that the frontal lobe tumor case becomes unduly dull and over-facetious, that the senile dement becomes forgetful of the immediate present but is accurately retrospective, that the alcoholic fabricates, the opium addict develops a moral turpitude, the epileptic becomes asocial and egotistical, and the brain trauma case becomes hypochondriacal The pathological personalities thus discovered in these psychotic states are the direct outcome of primary brain disturbance

And again, with such organic nervous diseases as brain syphilis, paralysis agitans, Huntington's chorea, and multiple sclerosis, to mention a few similar personality changes are to be noted But there is still another type of personality change in which as part of the picture of some physical disease not attacking the central nervous system directly or even indirectly, a mental change of some significance occurs Men like Draper, Wertheimer, and Kretschmer, working on the relationship of physical constitution to disease, are asking whether there might not be something in the physical makeup of a patient which renders him unusually susceptible to certain types of illness They aim to diagnosticate ulcer types, lung types, schizophrenia types, on the basis of stature, weight, and other anthropological features As a corollary, could it not be asked whether patients suffering from certain definite physical ailments

*Read before the Syracuse Academy of Medicine December 18, 1928

do not have as accompaniments specific mental or personality changes?

Before proceeding to some definite examples, two pre-eminent conditions that disturb personality should be considered. The first, the endocrine disorders, is mentioned merely to refer to the enormous literature that has been built up on the theme of the glands-regulating-personality, as one author labels his book. The second includes that pathetic experiment of Nature, which produced lesions in the basal ganglia of the brain as an expression of that protean disease, epidemic encephalitis. After several years of clinico-pathological investigation throughout the world, it would seem as though one more silent area of the brain has been heard from and that quite conclusively one can assert that emotional states are contigent in a great measure on the action of the nuclear masses lying below the pallium. The wide range of personality changes, from simple behavior disorders to gross malicious, and pathological conduct, as an aftermath of attacks of encephalitis, would seem to bear this out.

An analysis of almost any disease commonly encountered will disclose certain mental components. A few will be considered in brief, and then by way of further elucidation the numerous changes in personality provoked by tuberculosis will be outlined in greater detail.

John Hunter made the historical remark that he was at the mercy of any rascal who would provoke him. A victim of spells of angina pectoris, the ensuing excitement would promptly evoke a seizure. I wish to mention a sad experience in bringing on unwittingly an anginal spell in a patient by persisting, against his wishes, in taking some blood for a Wasserman test. In addition to this undue susceptibility to excitement, the anginal patient shows a peculiar feeling of anguish, the so called angor animi, and a premonition of immediate death, so much so that Seneca said that "to have any other malady is only to be sick, to have this is to be dying." As previously mentioned, patients with high blood pressure also show at times a tendency to be over-excitable. In cardiac disease in general, depressive mental states are often outstanding. Foster says that the mental state caused by cardiovascular disorders may be a pronounced psychosis or merely a change in the personality evidenced by diffidence and lack of initiative. Diabetes mellitus may be accompanied by a feeling of moroseness and a tendency towards hypochrondria, while some patients display an extraordinary degree of irritability, restlessness, and anxiety. Constipation dulls the mentality to a degree ranging from debility, torpitude, and lassitude, down to depression. I remember a case of Hirschsprung's disease with no bowel movements for over two months whose mentality, bordering on that of a low grade moron, cleared up phenomenally after a colon resection. In enteroptosis Osler says the first indication is to treat the existing neurasthenia. Also, in nephroptosis the nervous symptoms may run the various grades of hypochrondriasis, and even forms of insanity have been attributed to it. Why is it, again according to Osler, that a large proportion of cases of mucous colitis are nervous to some degree, that many of them have hysterical outbreaks, or are hypochondriacal and melancholic? Such patients, he adds, are self-centered individuals of a most distressing type. Hay fever patients become low-spirited. Bronchial asthma is often found in families particularly with irritable or unstable nervous systems. Depression and delusions may be present in pernicious anemia, noticeably as the disease advances. According to a recent article by Weil and Cahen in the *Paris Medical Press*, mental disturbances may make their appearance at any stage of the disease, varying from simple character modifications to dementia, with depressive or maniacal states. These symptoms subside on improvement of the blood picture. Fear and apprehension constitute the prevailing mental tone in exophthalmic goitre. Associated with the physical signs of pellagra there may be a simple mental retardation. Godard, in a recent number of *Clinical Ophthalmology*, discusses the influence of myopia of the personality. Carcinomas, occurring more often in late life, show a hopeless depression as a symptom of the age of the patient. Cassity, in an analysis of reaction types in cancer, summarizes as follows his observations. "In spite of the fact that these studies fail to establish conclusively a psychic foundation for somatic change, they at least validate the contention that the solution of the cancer problem will lack completeness so long as the psychic component be regarded as a negligible one." Neilson says that among the emotional disturbances in chronic infections of the nose and accessory sinuses are nervous irritability, exhilaration followed by depression, and phobias.

That toxic conditions, especially of a prolonged or chronic nature, exert as secondary manifestations certain changes in the personality is no more vividly substantiated than in tuberculosis. Apart from the mental attitude a patient may justifiably assume on realizing he has been seized with an invidious and well-nigh destructive ailment, an attitude such as depression or pessimism or forced indifference or buoyancy, there is undoubtedly something of a peculiar nature inherent in the tuberculosis itself that seems to predispose towards definite types of altered personalities.

The feeling of hopefulness so well known by the phrase *spes phthisica* which many patients manifest, has frequently been remarked upon. Osler says that victims with extensive cavities, high fever, and an inability to stir out of their beds will often make plans for the future in their confident expectation of recovery. Heinzelman,

in Nothnagel's Encyclopedia of Practical Therapeutics, speaks of a mental degeneration with optimism on the subject of health, encouraged, it is true, by the attending physician

Eugene O'Neill, with the astute observing powers of a great dramatist, has recognized this feeling of optimism In his play *The Straw*, which deals with the theme of tuberculosis, of which he himself was a victim, one of the characters, speaking of pulmonic patients, says that none of them really feel sick, adding that this state of mind is a pipe dream that keeps them all going

At the onset of the ailment there may be a tendency towards depression, or melancholy, or hypochondria In fact it is often the experience that extreme difficulty is encountered in differentiating between incipient tuberculosis and neurasthenic states However as the disease advances, the *spes phthisicorum* is predominant, and is in such marked contrast to the physical condition of the invalid that it often leads him to excesses

Heinzelman believes that there is something characteristic about the misunderstanding of the gravity of the illness, and tells of a colleague who pithily remarked that he never knew a consumptive who did not order new clothes shortly before his death Even physicians, he declares, when attacked by the disease, are not free from these self-delusions, he relates the incident of one who, despite his persistent fever, his uncontrollable delirium, and hemoptysis, continued to speak in hopeful terms of his bronchitis until within ten days of his death This hopeful attitude, in the opinion of Casamajor, especially in those tubercular patients in early adult life, is proverbial, and most likely depends more on the age of the patient than on anything in the disease itself

It often happens that the mood may vacillate very rapidly—the patient at one time being exalted to the heavens and shortly thereafter depressed to death Although intense worries follow every red streak in the sputum, correspondingly and naturally enough, there is a longing for contradiction and inspiration

Another manifestation of the effect of the disease on the mind is cited by R C Holliday in his Broome Street Straws The author refers to Camille Mauclair, who in his study of Watteau the painter, 'draws attention to the especially intellectual character of consumption, traces the action of this malady on the imagination, and the effect of this illness on the artistic organism sensibility, character and work' Extremes are noticeable, as there may be a diminution of the critical faculty, with deficient or abnormal energy for work, with impulsiveness, hesitancy, or obstinacy

In some patients it may follow that the intellect remains normal to the end, or at the most there is a diminished endurance with sluggishness in forming thoughts Again, in others, an emotional weakness is noted, accompanied by a lack of self-control, an instability leading at times towards ecstasy, general irritability, and a low-grade excitability

It is traditionally believed that consumptives are inclined to an excessive degree of sexuality Various explanations are offered lack of occupation to absorb the mind as a concomitant of the prolonged rest cure, the high nervous tension, and the consciousness of an apparently incurable disease with the desire to drain life to the dregs However this may be, it is the belief of some observers that this characteristic is overdrawn

A more extreme type of personality change is that which crosses the border to a psychosis or near-psychosis Church and Peterson conclude that the disturbance of nutrition and the mental depression may lead to an exhaustion or inanition delirium, followed subsequently by a melancholia or hallucinatory excitement There may be a real mental breakdown lasting months, or an acute mania may supervene

In DeFursan's Manual of Psychiatry it is noted that symptomatically, tuberculosis manifests itself most frequently by states of depression and abnormal sadness According to Chartier's classification there may originate four types of psychoses in connection with the disease the psychosis may arise during the course of the consumption, it may alternate with exacerbations of tuberculosis as a sort of tubercular equivalent, it may appear after an apparent cure, or it may show itself in a patient having latent tuberculosis

In England a special clinical form has been described under the name of tubercular insanity This is supposed to develop in three stages first there is an entire change of character, with unsociability, irrascibility, and a dulling of the proper enjoyment of life, after this comes the acute stage with ideas of persecution and mania, and finally a semi-stupor dominates the picture Whether it is admissible or not to consider these features specific for tuberculosis, it is indisputable that in no other disease does one see such a variety of definite personality changes as those accompanying the invasion of the bacillus of Koch

In conclusion, an endeavor has been made to point out the importance of studying the personality of the patient, for the aid that such an understanding may give towards a more accurate diagnosis and a more sympathetic and thorough treatment

ADRENALIN PROBE TEST IN NEUROSYPHILIS

By I J ARNSSON, M D, L M SACHS, M D, AND N E STEIN, M D, BUFFALO, N Y

IN 1924 Dr Muck of Essen, Germany[1], reported the following hitherto undescribed reflex phenomenon of the mucous membrane of the inferior turbinate, sprayed by adrenalin solution

If the anterior portion of the interior turbinate of a normal individual is made ischaemic by means of a spray of an adrenalin solution of 1 to 1,000 and a line is drawn upon it parallel with the floor of the nose with a probe, under moderate pressure, three or four times in the same manner as the well known dermographic test on the skin—the ischaemic mucous membrane immediately or shortly after the probing turns hyperaemic This hyperaemia after one to two minutes recedes and remains limited to the probed line only, being markedly visible on the adrenalin ischaemic background In from two to fifteen minutes the phenomenon disappears and the normal condition of the mucous membrane is restored.

In certain pathological conditions of the brain however, this test shows a different picture from that described In such cases the line produced by probing, instead of being hyperaemic, becomes white, and after the adrenalin ischaemia recedes, it stands up clearly on a pink background (Inasmuch as any instrumental cleansing or swabbing will irritate the delicate mucosa of the inferior turbinate, thereby interfering with the test—the patient is requested whenever necessary to blow the nose in order to free the mucous membrane of any secretions present)

The author referred to this as dermographia alba, but inasmuch as this term is already used in dermatology for a different phenomenon, and the test is made on the mucous membrane—the term of mucographia alba would seem to us more appropriate The mechanisms of this pathologic reflex phenomenon the author explains as follows [2] The nerve endings of the sympathetic system are irritated by adrenalin This results in a peripheral angiospasm The mechanical irritation of the same region excites in pathological cases an additional angiospasm, which is of longer duration than the one produced by the adrenalin spray Both irritations, the pharmacodynamic and the mechanical, re-inforce each other in the vasoconstrictor action Inasmuch, as in normal conditions the probed line is red, the white line must indicate an over-irritability of the vasoconstrictors i e an increased local sympathicotonus

For a better understanding the author quotes L R Miller's treatise on the "Anatomy of the Sympathetic Nervous System" The nerves of the cerebral blood vessels originate partly in the carotid and vertebral plexuses, also in the 3, 6, 9 10, 11, and 12th cranial nerves, which combined constitute the sympathetic and parasympathetic systems Nerve fibres from the upper sympathetic ganglion (ganglion cervicale supremum) build rete around the internal carotid artery and enter with it into the cranial cavities In the circle of Willis the carotid plexuses of both sides communicate with each other so that in case of a unilateral irritation of the sympathetic nerves of the neck region the innervation of the blood vessels responds equally in both brain hemispheres

That exceptions do take place is shown in cases of migraine which rightly is explained as a unilateral angiospastic irritation of the cerebral arteries

Muck was able to produce a mucographia alba in a normal individual by mechanical irritation of ganglion cervicale supremum in the naso-pharyngeal space pressing upon the ganglion by means of a probe So it follows that the mucographia alba is an expression of a state of over-irritability in the said ganglion

In a number of reports by Muck and J Barnewitz[3] the pathological reflex was found to be present in hemicrania sympatico-tonica, in epilepsy (however, it may be absent in intervals between attacks of either), in cases of a brain tumor, in all traumas of the skull with involvement of the blood vessels of the pia, and in cases of late, latent syphilis and neurosyphilis As for the last group the mucographia alba was found in accordance with the spinal fluid Wassermann in 86% of cases and in negative serology in 82% The authors have never found the pathological reflex in normal individuals, or in patients without involvement of the brain, or in arteriosclerotics

The fact of the presence of a pathological reflex phenomenon in late, latent syphilitics, which would give the possibility of a quick orientation in the office seemed extremely tempting to us First of all we wanted to make sure that this test is present in definite pathological conditions of syphilitics, and therefore, have chosen the neurosyphilitics and paretics with a well established clinical and serological diagnosis As a control we made tests on an equal number of patients with Dementia Praecox

The results of the tests in 100 cases are shown in the tables beginning on the next page

In this work we had splendid cooperation from the Superintendent and Clinical Director, Drs I J Furman and H L Levin respectively, of the Buffalo State Hospital, for which we are extremely grateful

The results of the first step of the work are shown in the table

B S = Blood Serum
S F = Spinal Fluid
Glob = Globulin
C G = Colloidal Gel
Chol = Cholestrine
C N S = Central Nervous System

Summary

1 Of 100 patients with neurosyphilis or paresis with definite clinical and serological characteristics, 99 showed in the adrenalin probe test the phenomenon of mucographia alba

2 Of 105 patients with Dementia Praecox, 4 showed mucographia alba limited to one side of the nose In all 4 patients the history revealed severe traumata of the skull, and in 3 of them A G, R M, and W Le M, scars with periosteal swellings were evident

3 The adrenalin probe test proved to be most satisfactory and valuable as a means of rapid orientation before the spinal puncture is performed

4 The presence of mucographia alba in paretics and neurosyphilitics make us believe that also the sympathetic system must be a seat of a certain pathology Whether the process is a specific one with the presence of spirochetal pallida in the main ganglia (cervicale supremum and sphenopalatinum) or the sympathetic rete accompanying the blood vessels, histological research will determine

It would be also of value to follow up the positive adrenalin test cases of latent syphilis with a negative serology, both in blood and spinal fluid, as reported by Muck, as to the later fate of such patients

An extensive examination in a clinic or dispensary with a large number of syphilitics of all stages would be necessary, as the invasion of the central nervous system may occur at a very early stage of the disease The prognosis of syphilis as to the later involvement of the C N S is of such importance as to warrant the use of every method which may help us solve this problem, and it seems to us that in the adrenalin probe test of Muck, we have a very fine adjunct in the diagnoses of pathological conditions in the cranial portion of the C N S

READ THE NEWS DEPARTMENT

The special reason for publishing the New York State Journal of Medicine is to inform physicians what the medical societies of the state and the counties are doing,—their accomplishments, plans, aspirations and ideals. These records are found in the department of "News Notes" which in this Journal begin on page 1212. They are not merely official minutes to be filed away and forgotten. They describe, explain and interpret the discussions that take place in the meetings and committee-rooms of the societies of the state, the districts and the counties. They are designed especially to inform and instruct those who hold office in regard to their duties and opportunities.

Get the habit of turning to the News Department of your Journal.

COMMITTEE ON PHYSICAL THERAPY

It is the opinion of the newly appointed Committee on Physical Therapy that the somewhat unsettled status of physical therapy will be best solved by the proper evaluation and practical application of physical measures by physicians themselves Attention is called to the short lecture course in Physical Therapy which the Committee on Public Health and Medical Education is ready to arrange free of charge for any County Society, and also to the more extended courses in postgraduate institutions The Committee disapproves of courses held by manufacturers of apparatus

Every general hospital should possess an adequately equipped department of physical therapy, under the direction of a competent physician Technicians are to be employed only to carry out some of the treatments prescribed by the physician and must work under his constant supervision As to technicians licensed to practice" physiotherapy under the troublesome physiotherapy clause of the Medical Practice Act they must be controlled by a strict code and be made subject to action of the Grievance Committee, while those of good standing and training should be given opportunities for institutional work The number of these registered physiotherapists is already four times as large as originally estimated, and it is urgently desirable that the legal requirement of a four year study be enforced, and licensure be based on this and a real examination

RICHARD KOVACS *Chairman*

THE SECRETARIES' CONFERENCES

IT is an accepted fact that the secretary of a county society is the member on whom the reputation and efficiency of the society depends If he attends to his work and is interested and active, then the society will have an influence in all medical affairs He, more than the President or any other member, IS the society

It is also an accepted fact that the office of secretary is best filled when the one who holds it is retained year after year The discharge of the duties of secretary require knowledge and experience which become more and more valuable as the secretary continues in office

The recent conference of the county secretaries of New York State reported on page 1212 of this Journal, discloses the fact that a large proportion of the secretaries conform to the two ideals Many secretaries have held office for several years, and have been regular attendants at the meetings of the State Society, and at the Conference of the Secretaries of the County Societies The secretaries are the leaders in the conferences, and what they say carries the weight of their experiences The practical value of the discussions in the State Conference has inspired an editorial review of what makes a conference worth while

The idea of the Secretaries' meeting arose spontaneously some twenty years ago by the secretaries voluntarily dining together once during the annual meeting The identity of the originators of the dinner seems to have been forgotten but the memory of the meetings of the first few years is still vivid in the minds of those who attended them The striking fact whose significance was not appreciated at the time, was that health officers constituted a considerable proportion of the original group who came together at the dinners The duty of doctors toward public health problems was frequently mentioned, but one prominent State Society officer two decades ago made an impassioned address in which he declared that the State Medical Society had nothing to do with the State Department of Health But the editorials of the New York State Journal of Medicine in those days often referred to public health problems although they seldom offered plans for their solution How different are conditions today when the State Society takes an active part in directing public health affairs!

County secretaries assembled in conference wish to hear of the new projects which are being introduced into county society work The old topics of scientific programs, economics and sociability are projects well standardized, and no longer hold the attention of the secretaries at their conferences The secretaries come together in order to learn how to introduce and carry out plans along the newer lines of medical progress The dominant topic that is now discussed in the medical societies of the State and of the counties, is that of civic medicine, or the practice of medicine by the County medical societies This newer form of the practice of medicine was evolved by a natural extension of the old custom that practice was confined to curative medicine given by an individual doctor to an individual patient for pay This was almost the only form of practice in existence twenty years ago when the meetings of the secretaries were started and when even the officers of the State Society opposed the entrance of the State Department of Health into any corner of the field of the practice of medicine and at the same time deeply resented the

health activities of lay organizations But the experiences of recent years have disclosed the fact that doctors must act as a group collectively and impersonally, if they would bring all forms of medical service to all classes of people, and hence there came to pass the practice of medicine by county medical societies A county medical society practices a very real form of medicine when it plans to bring diphtheria toxin anti-toxin within the reach of all people, it engages in medical practice when it plans measures to insure purity of milk, and the wholesomeness of water, it also practices medicine when it plans to detect and correct the defects of school children These and other forms of the practice of medicine by county medical societies are rapidly becoming standardized and accepted by physicians generally

The practice of medicine by county medical societies is an alluring subject in which not only secretaries, but also other physicians are interested Its promotion is the major object of two standing committees of the State Medical Society those on Public Health and on Public Relations, and it is mentioned in most addresses by State Society officers It will be a major activity of the county societies of the future for physicians must support its practice if for no other reason than as self-defense against the assumption of the great field of the practice of preventive medicine by the State

The topics,—how to make a scientific program, how to put on a social dinner, and how to collect bills—are no longer subjects for discussion, for the methods of doing them have been developed for years, but the practice of medicine by the medical societies of the state and counties is an exceedingly live topic whose discussion will interest secretaries of every county society

A careful reading of the reports of the Conferences of Secretaries of other states in the State Journals discloses two methods of conducting them

1 Addresses by prominent authorities

2 An experience meeting in which the secretaries tell what their societies have done

The experience meeting is by far the better of the two Practically every form of activity has been carried out by some county in New York State While the experiences of the counties have been varied, they may be used both for warning and for inspiration It is most interesting, for example, to hear one secretary tell of the failure of his county society to draw more than half a dozen members to a meeting, while the secretary of a similar county reports that the number attending his society is greater than the number of its members, because of their interest in the graduate courses conducted by the State Society

The most interesting experiences of all those told by secretaries are those in relation to the practice of medicine by the county medical societies When a secretary is interested in any subject, the other members of the society will be sure to follow his lead

The following conferences of the secretaries of medical societies have been described in this Journal in recent years

1 Luncheon meeting of County Societies, Journal of April 15, 1926 page 342

2 Formal Conference of County Secretaries, Journal of September 15, 1926, page 798

3 A M A Conferences of State Secretaries and Editors, Journal of December 1, 1926, page 998, and December 1, 1927, page 1326, and December 1 1928, page 1435

4 Michigan Conference of County Secretaries, Journal of July 15 1927, page 816, and July 1, 1928, page 824

5 Conference of County Secretaries of New York State, Journal of October 1, 1927, page 1094

6 New Jersey Secretaries' Conference, Journal of May 1, 1929, page 566

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO

Treatment of Typhoid Fever —The treatment of typhoid fever is discussed in two articles in this JOURNAL of October, 1904 One author lauds acetozone, which had a meteoric vogue and a fall equally rapid Its effect was ascribed to alleged antiseptic properties, and in a sturdy defense of the antiseptic form of treatment, the author wrote

"Osler has no confidence in antiseptics Yet, he says, he can vouch for the efficacy of several, 'Beta-Naphthol,' 'carbolic acid,' and 'iodine' This simply shows prejudice upon his part He swears by the Brandt method with results no better, if as good as Flint reported in the cases of lumbermen in the woods who had no treatment Thirsth and many others have advocated a combined eliminative and antiseptic treatment Its results were remarkable The serum treatment, both curative and for immunization, points to the proper method, or at least, to the principles of treatment, as does the antitoxin for diphtheria It simply deals with the toxins and in no wise, does it abort or cut short the disease itself That hygiene and sanitation has lessened the prevalence and virulence of typhoid is another proof of the value of antiseptic treatment That several thousand cases have been treated by antiseptic measures with mortality rate of less than 2 per cent should convince the most skeptical mind, even an Osler"

MEDICAL PROGRESS

Liver Extract in Pernicious Anemia—Prof H Schottmüller checks up on the progress of his anemia cases under liver extract treatment, and while he finds that deaths are increasing in frequency despite the latter he is not pessimistic He claims to have been the first man in Europe to test the American plan of treatment, in 1926, in an apparently hopeless case, the patient is living and well although he has had relapses This type of case is now well known—the patient who despite relapses manages to keep in good health with the use of liver extract The total material treated amounts to more than fifty patients in which the result with his treatment carried out alone was brilliant To this may be added 14 more patients who have had relapses and are still under observation So far as his own practice is concerned, no fatalities are mentioned, so that in speaking of mounting death rates he must refer to the experience of others or to mere vital statistics, according to which deaths from pernicious anemia still occur

Hans Schulten, an associate of Schottmüller restricts his paper to a study of the follow-up of 25 patients This shows that the treatment must be instituted as soon as possible and the patients should be under constant control during remission periods It should be our object, of course, to prevent relapses and to this end frequent blood examinations must be made A factor of importance in prognosis is the state of the nervous system The author is not explicit as to the nature of this mischief but in the case of three patients in whom death was not attributable to anemia outright, two fatalities were due to funicular myelitis with paralysis of the bladder and ascending urinary infection A third patient's death could not be explained as the patient dropped out of touch, but at last accounts he was having a remission from his anemia—*Münchener medizinische Wochenschrift*, August 2, 1929

Early Diagnosis of Pulmonary Tuberculosis—The entire number of the *Schweizerische medizinische Wochenschrift* for August 3, 1929, is given over to articles on this subject, the papers having been read before the Swiss Antituberculosis Union, session of March 17 last E von Romberg calls attention to the fact that apical infection may be found at autopsy which could not be disclosed in the clinic For that matter some apical changes are found in the majority of adults at autopsy While in many cases apical foci are latent, in others their presence is attended by general symptoms, although this coincidence is rare When foci are discovered and the cases are followed up for years, it is only in a small minority that the process is disseminated, so that even when the röntgen ray and other resources show evidences of apex infection this is not in reality a precocious diagnosis of consumption if nothing ever develops In certain cases the infiltration develops rapidly, cavities likewise form rapidly, and it is here that an early recognition does the most service In the paper by H Alexander the author discusses the technique, the causes of wrong diagnosis, etc He quotes Sahli's statement that in examining for early pulmonary foci not merely the lungs but the entire organism should be investigated Especially in patients who appear to suffer with neurasthenia, chlorosis, gastric disorders, etc, should we examine the apices of the lungs Auscultation and percussion have fallen somewhat into disuse of late years, owing to the advances in bacteriology and röntgenology, but this is a great mistake To rely purely on the r-ray is not justifiable The author depends to a large extent on the proper use of the tuberculin reaction and lays stress on the possibility of confusing tubercle with certain other diseases

Reinfection from an Old Apical Tuberculosis—Prof Ch Bäumler reports 4 cases which show how an old apical focus of latent tuberculosis can become activated Examiners for life insurance or military service sometimes find evidences of these foci, occasionally of an old cavity which communicates with the bronchial tree. Although the subject may seem in excellent health a small blood vessel in the lining of this cavity may rupture and cause hemoptysis We do not know just how this local infection originally develops, but it could take place in childhood or adolescence A complete clinical history of such a patient would probably disclose that at some period there has been a short febrile attack with physical signs implicating an apex This focus, become relatively harmless, may be activated by strenuous exercise involving deep breathing, the chief symptom being hemoptysis or the appearance of bloody sputum Of four cases cited the first occurred in a young man in apparent good health who in running to catch a train brought on hemoptysis He was put to bed at once but a tuberculous bronchopneumonia developed from aspiration and carried him off in a few weeks The second patient, unusually robust was sent to Davos after an attack of hemoptysis, and subsequently a focus of tuberculosis until then latent, was discovered He kept well until on one occasion after dancing, he again spat up blood and had an elevation of temperature He was at once ordered to bed, and died two days later The

autopsy showed a large cavity in one apex with foci of pneumonia The author had evidently expected to find acute miliary tuberculosis, but this was absent The third patient appeared in perfect condition on one June 22, but in a week was dead, an attack of hemoptysis having led to the discovery of a lobular pneumonia and acute miliary tuberculosis The fourth case was a duplicate of the third The author holds that any person having one of these old and apparently latent apical foci should never take violent exercise, and students who enter college should be examined for such foci—*Klinische Wochenschrift,* August 6, 1929

A Case of Complete Auriculo-Ventricular Dissociation with Fibrillo-flutter—B Solomjany and M Boukspan of Odessa give a very short report of a case of this nature with tracings After Fredericq had shown in experiments in 1905 that complete blocking could occur with auricular fibrillation clinicians were able to show that the same phenomenon occurred in human pathology and authors began to speak of the "Fredericq phenomenon" in man Cases thus far reported have been relatively few so that the authors feel at liberty to add another A man of 65, robust up to 3 years before, noticed then that he suffered from effort dyspnea and vertigo He neither smoked nor drank and had never had syphilis Physical examination revealed little There was a slight murmur after the first sound, both sounds were slightly muffled, and there were some premature contractions off and on without compensatory pause The left ventricle was somewhat enlarged The radials were hard and rigid and there was a bradycardia of 30-32, not augmented on exertion Numerous electrocardiograms were taken and showed typical complete dissociation The rhythm could not be modified by amyl nitrite nor atropine Continuous study of new tracings brought out the existence of fibrillo-flutter, sometimes termed impure flutter The usual causal factors of this condition are arteriosclerosis and syphilis and in this case the former was accused, along with sclerosis of the myocardium Without doubt the vessels in His's bundle were altered and the bundle itself suffered secondarily Lesions of the vessels irrigating the myocardium of the auricles were followed in turn by lesions of the myocardium itself Study of the tracings shows the coexistence of a lesion of the right branch of the bundle—*Archives des maladies du cœur,* May, 1929

Role of Masticaton in the Pathogeny of Alveolodental Pyorrhea—G Pitsch refers to a case which led to a series of researches on his part A man of 62 of robust health and with normal mastication was obliged to chew on one side of his mouth for a time and during the ensuing two months retraction of the gum of the first upper premolar occurred, with suppuration and final loss of the tooth which was easily pulled because no alveolus remained After this it was noted that all three of the lower molars were also affected with pyorrhea, loosening being one of the first symptoms The author has seen a number of cases in which the patients were able to trace the process There is no such affection as dry pyorrhea although there is a prepyorrheic stage which is proof enough that the microorganisms appear only after the disease is established and cannot possibly give rise to the disease itself To return to the case history, the three molars mentioned above were not affected in the same manner for there was no cul-de-sac in connection with the third molar and no suppuration, although with each of the first two molars there was a deep cul-de-sac with abundant suppuration All three teeth, however, were loose The author was able to combat the suppuration in the purulent teeth yet this did not arrest the progress of the disease directly It became possible, however, to obliterate the cul-de-sac when the tooth again became firm The author, therefore, adopts the belief that the disease is due to defective mastication Study of the teeth of primitive mankind shows teeth worn by mastication Calculus is often seen but evidently was insufficient to lead to pyorrhea. In the case narrated there was absence of calculus Teeth of primitive women who chew seal leather to soften it are quite free from pyorrhea while among primitives who live on soft food pyorrhea is common and severe—*Bulletin de l'Académie de Medecine,* June 25, 1929

Blue Sclerotics—H Paal has recently come upon a family in which blue sclerotics have been handed down for generations Before this episode he had also studied this condition with Wiechmann from the clinical angle Usually it is associated with otosclerosis and brittle bones The scleral anomaly might also be known as thinning, for it is the defective development of the membrane which causes the uveal pigment to show through it The otosclerosis has been attributed to two factors—structural alteration of the petrous bone and labyrinthine calcifications, both of which are readily made out in Rontgen plates Bone brittleness is ascribed to a disturbance of the calcium metabolism Nearly all the bones show evidence of atrophy which is largely restricted to the shafts of the long bones and affects the cortical lamina Other anomalies found have been calcium deposits in the lungs

which were not connected with tuberculous foci The anomalies transmitted by heredity are especially the blue sclerotics and the brittleness of the bones In the family under discussion blue sclerotics could readily be traced through four generations The author examined personally 36 direct members of this family and found the anomaly in 17 while 19 were exempt All 17 showed the blue sclera while 3 had had fractures and 15 showed anomalies of bone in röntgenograms All of the cases traced back to one stem-father who had the blue scleras and brittle bones but was not deaf The heredity seems to be dominant without any preference as to sex Further research into the medical histories of members of this family showed frequent occurrence of nose bleed of obstinate character during childhood One female also had poorly calcified teeth, and serum calcium determination showed this to be near the lower level of the normal in one patient and above normal in one—*Klinische Wochenschrift*, July 9, 1929

Epidemic Hiccup—A Salusbury MacNalty calls attention to the occurrence of a number of cases of epidemic hiccup in England during the first two months of the present year and previously, more particularly in 1919 1920, and 1924 In a fairly typical case the illness begins with a mild feverish attack of nasopharyngeal catarrh which may simulate influenza or a "cold in the head" The pulse rate is slowed From 25 to 48 hours after the onset the patient is suddenly seized with a persistent rhythmic hiccup which continues incessantly all day, interferes with eating and talking, occasionally causes vomiting, and ceases only when the patient succeeds in obtaining sleep The duration is usually from twenty-four hours to two or three days but may last as long as a week As a rule there is complete recovery from the attack and an absence of complications or sequelæ The conception of this affection, epidemiologically, is similar to that of various epidemic diseases of the nervous system Clinical experience and published reports lead one to believe that males over forty years of age are usually the subjects of the malady In an outbreak in Rheims it was definitely stated that children were not affected The degree of infectivity is not high Economo recorded hiccup as a complication of encephalitis lethargica in 1917, and MacNalty noted it in five of his series of cases in 1918 In the widespread epidemic of encephalitis lethargica in England and Wales in 1924 epidemic hiccup was also widely prevalent, and was seen in definite association, for instance in the same household, with encephalitis lethargica In practice it has been found that epidemic hiccup must run its course In the severe cases the patient should be confined to bed Sedatives such as bromides may be given and occasionally relief is experienced when belladonna or cajuput oil is administered If the paroxysms greatly distress the patient and prevent him from sleeping, morphine combined with atropine may be of help—*The Lancet* July 13, 1929, ccxvii 5524

Contribution to the Study of Hereditary Tuberculosis—Brindeau and P Cartier believe that this affection, even if rare, is more common than has been thought The work of a number of investigators has shown that a tuberculous mother not so rarely infects the product of conception, the bacillus passing through the placenta This, in the experience of the authors, may happen without the slightest lesion of the latter, even microscopic This fact need not astonish us for it has been shown that even a leucocyte may pass through a placenta absolutely sound The bacillus might therefore pass through in the free state or within a leucocyte It is also possible to find the bacillus in the blood of the cord, in the ganglia and viscera of the fetus, etc There are two methods available to demonstrate such facts, the first being inoscopy, which is simple and certain It may be applied to the maternal or fetal blood and, after centrifuging, the bacilli will be found in the clot The process may be tedious and time consuming in some cases when many slides must be made from the clot The other and indirect method is that of inoculation of the guinea pig This test may result negatively, even if the tissues are infected, when the bacilli are very few in number Again the resistance of the animals varies extremely, for while some succumb readily to the infection others live for many months The authors began their investigation in April, 1927 and studied 34 tuberculous women who were confined in the Tarnier Clinic In 29 of these the blood of the cord was studied by inoscopy and 30 inoculations were made In 26 women both tests were made One or the other test was positive in 13 women and in four of these both were positive Both tests were surely negative in but one case Other tests were vitiated in some way and could not be used in the statistics—*Bulletin de l'Academie de Medecine*, June 18 1929

Lymphogranuloma Inguinale in Relation to Anorectal Syphiloma—Some years ago Frei and others succeeded in separating an undescribed affection of the groins from chancroidal bubo Various names have been bestowed on it but Frei's lymphogranuloma inguinale seems to have been generally adopted Dr Alice Koppel, an assistant of Frei, seeks

to show that what has been known in the past as anorectal syphiloma may be affiliated with the inguinal affection, and in the latter part of 1928 she with Frei reported five cases, four of them in women Both the syphilitic and tuberculous tests were positive while chancroid and gonorrhea could be excluded It was thought at the time that lues and tuberculosis could so modify the soil that the new disease, the nature of which is as yet unknown could assert itself Since the publication of this report every patient with lymphogranuloma has undergone a careful rectal examination A woman of 35 with lymphogranuloma was found to present papillomatous growths about the anus with a stricture of the rectum 8 cm up, which admitted but two fingers This patient had had both gonorrhea and syphilis while chancroid and tuberculosis could be excluded Quite recently a woman of 24 presented herself with apparent hemorrhoids with rectal ulcers and passage of pus The genitals were normal but in the right groin were scars with a history of suppuration Frei's test for lymphogranuloma was positive The Wessermann and tuberculin tests were negative The last patient seen to date was a woman of 45, free from syphilis and tubercle There was an ulcer of the posterior commissure and bilateral enlargement of the inguinal glands with Frei's skin test positive for lymphogranuloma A secondary swelling of the right labium majus developed The author does not discuss the relationship of this affection to esthiomenus of the vulva, although a connection is often evident—*Klinische Wochenschrift,* July 8, 1929

The Early Diagnosis of Pernicious Anemia by the Halometer—Frank C Eve, writing in the *British Medical Journal,* July 13 1929, ii, 3575, states that the position of patients suffering from pernicious anemia has been revolutionized by two discoveries (1) the curative effect of liver and hydrochloric acid, (2) the diagnosis of pernicious anemia by finding enlargement of the red cells—a feature which is always present, and which, apparently, is the first to appear and the last to go By the halometer, a clinical instrument which instantly measures the size of the red cells, this latter information becomes available to the general practitioner, and the liver cure can be instituted at a far earlier stage These remarks apply also to subacute combined degeneration of the spinal cord, but not so absolutely, because occasionally the neurotoxic factor in pernicious anemia is at first unaccompanied by the hemolytic factor The course of action in these diseases is quite clear In all suspicious cases ascertain if the red cells are enlarged If so, confirm this by the color index, or prove achlorhydria by a fractional test meal Give a half a pound of liver daily, or the corresponding amount of extract, and if this causes the red cells to become normal in about two months the diagnosis of pernicious anemia is established Extract suspicious teeth, and remove septic tonsils, or keep them clean by the suction method Give 6 drachms of hydrochloric acid daily, this must be taken for life to prevent streptococci from again obtaining a foothold in the upper bowel The author describes the halometer, a small instrument, which packs in a doctor's bag, and measures the diffraction halo of the red blood cell The large red cells characteristic of pernicious anemia produce halos which are smaller than normal Normal halos are 4·6 to 4·9 degrees, while those of pernicious anemia or subacute combined degeneration are 4·4 degrees or less Blood halos, around and about 4·5 degrees in width are suspicious Very small colorless halos indicate pernicious anemia in an advanced stage Hazy colorless halos of normal size are characteristic of secondary anemia

A New Conception of Beriberi—According to Alfred Gigon of Basle, several Japanese authors mentioned by him have introduced a new line of investigating beriberi of fowls, the results of which appear to antagonize the belief that the disease of fowls is an avitaminosis, whatever it may be in mankind The author had reached the same conclusion 6 or 7 years ago, to wit, that although a deficiency factor might be present, such alone is insufficient to explain the disease To produce the latter we give the birds a diet of pure carbohydrate Vitamins are of course lacking, but the mere fact af feeding exclusive carbohydrate does something to the organism, to wit, deranges completely the entire carbohydrate metabolism Vitamin addition does not correct the condition and the animals die, and at death they are found to have no glycogen in either liver or muscles Moreover an acidosis develops in such animals, especially when on a diet of grape sugar To what extent is this acidosis responsible for the fatal outcome? The author with two colleagues sought to set up a mineral acidosis by feeding the birds with various acids and ammonia compounds Mineral acids do not lead to increase of ammonia bodies in the blood, but this result follows feeding with urea, ammonium chloride, or ammonium carbonate The glucose and ammonia-formers in the blood appear to be necessary to each other for the proper functioning of the economy Incidentally the author thinks that we may have to abandon our conception of diabetic acidosis He points out that in diabetes we also have a tendency to polyneuritis which may be akin to the fowl disease—since both are characterized by a complete breakdown of carbohydrate metabolism—*Schweizerische medizinische Wochenschrift,* June 22, 1929

LEGAL

THE ADMINISTRATION OF JUSTICE IN ENGLAND

No one who has studied or observed the manner in which justice is administered by the English courts can fail to compare it with the administration of justice in America, to the great disadvantage of our own country The sensational, mawkishly sentimental and theatrical manner which has characterized a number of criminal trials here has served to accentuate and bring into bold relief the calm, quiet and peaceful dignity of a trial in England In civil litigation too, we lag far behind our English cousins Justice delayed is justice denied, is the plea of Bench and Bar In England cases are disposed of with a celerity that is amazing to one accustomed to our methods

England, of course, has the advantage of centuries of precedent and tradition Respect for the law is ingrained in an Englishman The English courts are administered in a manner calculated to impress its people with the solemnity and majesty of the law, with the result that the disgraceful perjury which is rampant in our courts, is almost wholly unknown in England

The English are not a litigious people We are The difference between us in that respect in large measure is due to the difference between the character and standing of the English Bar and our own In England before a man is admitted to the Bar he must demonstrate that he possesses the intellectual, cultural and moral qualifications entitling him to belong to a learned and honorable profession The American Bar has good reason to be proud of the thousands of splendid men included in its roster, but unfortunately, in increasing numbers, there are lawyers who yearly come to the Bar in every state in the Union without the intellectual and cultural qualifications which a lawyer should possess, and most unfortunate of all, without any real conception of the obligations which attach to membership in the legal profession

It is not possible to point out in an editorial of this character all of the differences in court procedure here and in England, but we shall comment on a few of them In the trial of a criminal case in England, the judge is permitted to comment upon the evidence, that is to say the law permits him to give to the jury the benefit of his opinion on the probability or improbability of the testimony of any witness, although instructing the jury that they are not bound by his opinion and that they are the sole judges of the facts In our state courts this privilege is denied the presiding judge When a criminal is convicted in the trial court here, it is generally only the beginning of a long legal battle With appeals, new trials and resort to all the legal advantages which our law gives to a criminal, it is often years before punishment is meted out to him for the crime for which he has been convicted, and unfortunately, in many instances he escapes punishment entirely In England the reversal of a conviction by the Appellate Courts is rare Punishment follows swiftly upon conviction

In civil litigation an incident narrated by Mr Justice Joseph M Proskauer of the Appellate Division of New York City, during the trial of a case in England, is interesting, explanatory and significant He says

"I recall the trial of an accident case I heard in England A witness was asked to describe the accident and then was asked, To what do you attribute the accident? The answer was succinctly given that the chauffeur had not been looking where he was going

'I should like to parallel the incident in an American court The witness would be asked what he saw, he would probably endeavor to say that he saw the chauffeur was not looking where he was going A motion to strike this out as a conclusion would be promptly made and promptly granted The question would be repeated The bewildered witness would again approximate to a statement of what he really thought he saw, namely, that the chauffeur had not been looking, a new motion to strike out made and granted would be followed by an admonition of the trial Court to the witness to be careful not to give his conclusion, but only what he saw, and the situation would end with the collapse of a witness, now no longer bewildered but utterly stupefied by the absurdity of a system of law which would not permit him to tell the story of the accident exactly as he would relate it to any human being in the world"

And comparing our judicial system with that of England, Judge Proskauer draws the following conclusion with respect to our methods

Most of the time in our courts of law is not consumed with the adducing of evidence it is largely occupied with controversy and discussion as to the manner in which the evidence shall be adduced In this practical country, immeasurably more than in any other civilized country in the world, there are consumed in the courts vast quantities of priceless time with wholly impractical contention regarding forms of questions the attempts to draw a sharp dividing line between fact and opinion, the unending chatter as to whether the question calls for a conclusion, the

meaningless formulation of and assault upon interminable hypothetical questions The law of evidence is not an end in itself and we should cease making it our objective It is purely adjective law, simply a method by which to ascertain facts

In England in a civil litigation all of the proceedings prior to trial are referred to a Master The salutary effect of this system is very well stated in a scholarly paper by Edson S Sunderland, Professor of Law of the University of Michigan, entitled "Appraisal of English Procedure" Professor Sunderland says in part

"It is, of course, impossible to determine how much time is saved by these preliminary admissions, answers to interrogatories, and disclosures of documents, but an observer who compares the time used in an English trial with that ordinarily consumed by a similar trial in the United States, and notes the points at which speed is secured by reason of prior discovery, might perhaps estimate a fifty per cent saving With the facts on each side mutually understood by both parties when the trial opens, leading questions no longer become objectionable on many features of the case, and the witness is brought at once to the point in controversy with no waste of time over formal preliminaries, the necessity for cross-examination is greatly reduced, and it is frequently omitted altogether the formal introduction of evidence is largely dispensed with, for complete typewritten sets of copies of the documents previously inspected are already in the hands of the judge and of counsel on each side when the trial begins, and they are usually introduced by consent, formal admissions of facts and answers to interrogatories, eliminate entirely many features of the case which with us would call for extensive proof With the element of surprise largely out of the case at the opening of the trial, there is no occasion for that manœuvering for advantage, that vigilant and tireless eagerness to insist upon every objection, with which we are so familiar, and which not only prolongs and complicates the trial but helps to make the outcome of an American law-suit turn as much upon the skill of counsel as upon the merits of the case

"Our bar has always been inclined to fear and distrust disclosure before trial They have thought it would tend to produce framed-up cases and perjured testimony But it must not be forgotten that want of disclosure causes great delay, inconvenience and expense in the preparation for trial, seriously prolongs the trial itself to the prejudice of the parties, the witnesses, the jurors and the court, and results in a defective and inadequate presentation of the real merits of the case, thereby diminishing public confidence in the ability of the courts to find the truth In the development of the law of evidence, every reform has been opposed on the same ground—that it would tend to encourage perjury It is hard to realize that no longer ago than 1851, Lord Brougham's Act for the first time made parties competent witnesses in civil proceedings in the superior courts There was great dread of the act, lest the interest of parties should encourage false swearing But the fear felt by the legal profession was groundless, as events have proved The history of reforms both in pleading and in evidence has shown continuous tendency to remove more and more restrictions on the disclosure of the truth The spirit of the times calls for disclosure, not concealment, in every field—in business dealings, in governmental activities, in international relations, and the experience of England makes it clear that the courts need no longer permit litigating parties to raid one another from ambush"

In recent years there are hopeful signs pointing the way to a reorganization of our judicial system Your counsel is of the opinion that we would do well to take the English system as a pattern for the suggested reform in our own administration of justice

SYPHILITIC DEPRESSION OF THE NASAL BRIDGE—CLAIMED NEGLIGENCE IN OPERATION AND TREATMENT

The complaint in this case alleged that the plaintiff had been suffering from an obstruction in his nose which impeded and interfered with his breathing, that he engaged the defendant, as a physician, to treat him for his ailment and that the defendant advised him that an operation on his nose was neccessary and desirable, that in consequence of the advice so rendered the plaintiff submitted to an operation in which it was claimed that the defendant did attempt to graft a piece of bone from the plaintiff's rib on the septum or one of the interior bones of plaintiff's nose, at which time the plaintiff claimed the defendant stated that the grafting process employed would raise the bridge of the plaintiff's nose and cure the plaintiff of his ailment

The complaint further charged that the plaintiff was treated for several months thereafter by the defendant, at which time the defendant advised the plaintiff that another operation was necessary It was claimed in the complaint that the defendant again operated upon the plaintiff, and while the plaintiff was under an anesthetic and without his knowledge or consent, the defendant removed a large flap or portion of the skin from the bridge of the plaintiff's nose and removed the dead or necrosed bone from the interior of the plaintiff's nose

The complaint further charged that the defendant cut a large flap of skin from the forehead of the plaintiff, and attempted to graft the same across the bridge of plaintiff's nose where he had removed a large portion of tissue and skin and thereafter took large pieces of skin from the plaintiff's neck and attempted to graft the same upon the plaintiff's forehead where he had removed healthy skin and tissue over an area of approximately four by two inches The plaintiff claimed that the defendant in the said operations and treatment was negligent and careless

The plaintiff was a man about fifty years of age On the first occasion when the doctor examined him he found a syphilitic destruction of the membrane of the nose and empyema of the left antrum, with necrosis of the bony walls A notation on the hospital record at that time showed that the plaintiff's nose had always been depressed The patient consented to an operation

After the patient's consent had been obtained, the defendant operated upon him This operation consisted of an incision through columella skin undermined, nasal process of maxillae chiseled through, graft taken from right costal cartilages one cut to fit and put in place the other buried in chest wound, wounds closed—nasal with horse hair, chest with silk worm The day after the operation the patient's temperature rose from 102 to 105 and for the next three or four days it varied between 105 and 101 Infection was present as indicated by the bacteriological examination of the septum which showed staphylococcus, streptococcus hemolytic, pneumococcus The blood report for syphilis taken at that time showed negative The blood report showed leukocytes, 11,200

Because of the infection, the defendant removed the cartilage under a local anesthetic about four days after the operation The plaintiff remained in the hospital for two weeks The infection cleared up, the nose healed and he was able to go home The operation was in all respects successful

After the first operation for some period of time the doctor continued to treat the plaintiff's nose inside and outside and then the plaintiff consented to a second operation known as a rhino-plastic lining At this operation the defendant scaled off a piece of skin from the plaintiff's forehead and without removing the skin entirely, pushed the upper end of it down through his nose so as to make a lining for the inside of his nose This was left in place until about a month later when the defendant did a Wolf graft, which the defendant describes as follows Incision through Wolf graft from forehead to nose relieving attachment to nose Graft scar tissue removed and prepared for replacement in forehead Proud flesh from old scar of forehead removed and flap replaced sutured with horse hair Small triangular area devoid of skin part of graft left on nose Small triangular area removed from right side of neck to replace nasal piece of graft Fibrous c t in nose and sutured skin to complete contour of face and nose Bone graft transplant contemplated at a later date

For about four months thereafter, the defendant at various times saw the plaintiff and gave him treatment consisting of irrigating the inside of his nose with magnesium of sulphate 5 per cent, and the defendant also gave him injections of iodine and mercury salicylate to guard against a recurrence of the syphilis When the defendant last saw the patient, the grafting was a complete success, the outside of the nose was healed and he had no infection

The doctor requested the patient to return, and told him that he would take some skin from his leg and insert it on his forehead where he had a scar but the patient never returned

The case came on to be tried, and the plaintiff wholly failed to prove any negligence on the part of the defendant or any lack of consent as to the operations performed The court, on its own motion without submitting the case to the jury dismissed the complaint, holding that there was not the slightest evidence of any negligence on the part of the defendant

NEWS NOTES

THE CONFERENCE OF COUNTY SECRETARIES

The Third Annual Conference of the secretaries of the county medical societies of New York State was held in the De Witt Clinton Hotel Albany, on Tuesday, September 10, 1929, with Dr D S Dougherty, Secretary of the State Society, presiding

These conferences were evolved from an annual luncheon which the secretaries held during the annual meetings of the Medical Society of the State of New York, the last one of which was held in Syracuse on May 13, 1925, and was reported in the Journal of June 1925, page 762 The seventeen secretaries who were present at that time voted to request the Council of the State Society to authorize the formal conferences annually

The first conference under the auspices of the State Society was held in Albany on September 2, 1926, with forty secretaries present, as was reported in this Jounral of September 15, 1926, page 798

The second conference was held in Albany on September 15 1927 with thirty-eight counties represented, and was described in this Journal of October 1, 1927, page 1094

No conference was held in 1928

This year's conference was attended by the secretaries of thirty-two counties, as follows

County	*Secretary*
Allegany	L C Lewis
Cayuga	W B Wilson
Chautauqua	E Bieber
Clinton	L F Schiff
Columbia	L Van Hoesen
Dutchess-Putman	H P Carpenter
Erie	L W Beamis
Essex	L H Gaus
Fulton	A R Wilsey
Greene	W M Rapp
Herkimer	W B Brooks
Kings	J Steele
Livingston	LeG A Damon
Monroe	J P Henry
Montgomery	W R Pierce
Nassau	Mr Louis Neff lay-secretary
New York	D S Dougherty
Niagara	G L Miller
Oneida	W Hale, Jr
Onondaga	L W Ehegartner
Otsego	A H Brownell
Queens	E E Smith
Rensselaer	W B D Van Auken
Schoharie	H L Odell
Steuben	R J Shafer
Suffolk	E P Kolb
Sullivan	L C Payne
	and C Rayevsky (President)
Tioga	W A Moulton
Tompkins	W G Fish
Ulster	F H Voss
Washington	S J Banker
Wyoming	G S Skiff, (President)

The State Society was represented by

Dr J N Vander Veer	President
Dr W H Ross	President-elect
Dr D S Dougherty	Secretary
Dr Peter Irving	Assistant Secretary
Dr J S Lawrence	Executive Officer
Dr Frank Overton	Executive Editor
Dr T P Farmer	Com on Med Editor

The gathering was almost a reunion of old friends, for seventeen of the secretaries present had attended the conference of 1926

Moreover, those attending this year's conference had sent the greater proportion of the reports of society meetings which have been published in the Journal during the last three years, 14 out of the 29 reported in 1926, 23 out of the 37 reported in 1927 and 17 out of the 32 societies whose meetings were reported in 1928

The topic for discussion was 'How to Arouse Interest in County Medical Societies'

Dr F H Voss, of Ulster County, showed graphs of the attendance at his county society Ulster County has 74 members, of whom 40 are in the city of Kingston, 17 are within a radius of fifteen miles of the city, and 15 live beyond the fifteen mile radius Six meetings were held in 1928 and were attended by a great preponderance of city doctors, six of whom attended all the meetings, and 35 attended at least one while only two members living beyond the fifteen mile limit attended any meeting at all There was little interest in the Society among the members in the rural districts

Dr L F Schiff, of Clinton County said that the problem in his county was like that in Ulster The city of Plattsburgh supplied the doctors who took the most interest in the Society Questionnaries had been sent to all the doctors in the county asking what feature of Society activity they wanted, and the results were disappointing in that the members did not seem to care for scientific instruction Dr Schiff suggested that the scientific programs be turned over to the District Branches meetings, and that the

County Society should hold only business meetings, but keep an office in order to be in touch with the State Society

Dr L C Payne, of Sullivan County, reported that similar conditions had existed in Sullivan County up to five years ago, but that now the County Society was very much alive The attendance at its meetings it now about thirty-five while there are only about thirty members, Dr Payne ascribed the renewal of interest to the post-graduate courses which were held under the auspices of the State Committee of Public Health and Medical Education The members of the County Society are also active on the boards of voluntary organizations and direct their activities Dr Payne considered that a dinner, which is also held in connection with the county society meeting, was a great attraction

Dr L C Lewis of Allegany County said that his society meets for a luncheon and then an afternoon meeting with one local speaker and one from outside the county The attendance is very good, but the Secretary stimulates the members by a personal letter to each one When he does not send a personal reminder the attendance immediately falls off

Dr G S Skiff, of Wyoming County said that his county society showed interest in economic topics, but that scientific subjects came first His society was actively interested in civic affairs to such an extent that the Board of Supervisors asks a representative of the county society to come before it each year and explain the medical needs of the county with a special reference to appropriations for the County Hospital and the Laboratory

Dr A H Brownell, of Otsego County spoke of the staff meetings of the three hospitals of the county, but he said that the physicians also keep up their interest in the County Society, an average of seventeen members attending each of the four meetings held each year Post-graduate courses have increased the interest of the members of the society

Dr W B Brooks of Herkimer County spoke of seven faithful men who have kept up the County Society, while many of the other members were saying that they did not care who runs the Society or how it is run

Dr J N Vander Veer, President of the State Society speaking for Albany County, described the efforts of the County Society to arouse interest by holding meetings in Cohoes, and Watervliet, as well as in Albany, but the result was that the meetings were attended mainly by the doctors of the place in which the meeting was held He also said that rural doctors wanted programs on how to do things, rather than on ultra-scientific subjects

Mr Louis Neff lay-secretary of Nassau County described the renewed interest which came when the society began to meet in a Country Club and to start the meeting with a supper Nassau County had conducted over twenty postgraduate lectures held in the Nassau Hospital The biggest meeting of the Society was on the subject of establishing an agency for the collection of doctors' bills, when the attendance was 110 out of 170 members The agency is now in successful operation with Mr Neff in charge The Society has recently established a Monthly Bulletin which emphasizes the work of the committees, especially those having relations to voluntary health organizations of the county

Dr Dougherty commented on the fact that Nassau was the only County employing a lay-secretary, but he urged every Society to make liberal provision for clerical assistance for its secretaries and president

Dr W G Fish, of Tompkins County said that his society was holdings ten meetings a year, but he thought that four would be better The Society was taking an active interest in civic affairs

Dr G L Miller, of Niagara County, said that Lockport and Niagara Falls each had an Academy of Medicine which held the interest of the doctors, but the County Society sometimes held its meetings in connection with the Academy The County Society holds its meetings in different places in rotation, but the attendance is always largely from the city in which it is held

Dr L W Beamis, of Erie County the only woman Secretary in the State spoke of the success of the programs on economic topics, and deplored the ultra-scientific subjects that were sometimes put on the programs

Dr W B D Van Auken, of Rensselaer County, brought up the subject of uniform cards on which data of the members could be kept and asked that the State Society supply them There was considerable discussion on the form of the cards, but it was finally decided that all the objects to be attained by the cards were already provided by the four-page folder which was supplied by the State Society for the purpose of recording the data of new members

Dr W Hale, Jr, of Oneida County, said that his Society increased the number of its meetings from four to six a year with a loss of interest which was regained when the number was restored to four One meeting is held in Rome, two in Ithaca, and a meeting, the summer meeting, is a social picnic held in a country resort

Dr Hale said that at the last Secretaries' Conference, two years ago, he had reported that there was a division of opinion among the doctors regarding the site for the County Tuberculosis Hospital, and that there was also a conflict between the doctors and the Board of Supervisors, in which the Board had won but now the doctors are taking an interest in civic affairs to such

Moreover, those attending this year's conference had sent the greater proportion of the reports of society meetings which have been published in the Journal during the last three years, 14 out of the 29 reported in 1926, 23 out of the 37 reported in 1927 and 17 out of the 32 societies whose meetings were reported in 1928

The topic for discussion was 'How to Arouse Interest in County Medical Societies"

Dr F H Voss, of Ulster County, showed graphs of the attendance at his county society Ulster County has 74 members, of whom 40 are in the city of Kingston, 17 are within a radius of fifteen miles of the city, and 15 live beyond the fifteen mile radius Six meetings were held in 1928 and were attended by a great preponderance of city doctors, six of whom attended all the meetings, and 35 attended at least one while only two members living beyond the fifteen mile limit attended any meeting at all There was little interest in the Society among the members in the rural districts

Dr L F Schiff of Clinton County said that the problem in his county was like that in Ulster The city of Plattsburgh supplied the doctors who took the most interest in the Society Questionnaries had been sent to all the doctors in the county asking what feature of Society activity they wanted, and the results were disappointing in that the members did not seem to care for scientific instruction Dr Schiff suggested that the scientific programs be turned over to the District Branches meetings, and that the

Dr Farmer also argued that the State Medical Society should give wider publicity to news of its activities, and that the County Societies should report their meetings and lectures and the support which they are giving to the work of lay organizations

The Secretaries dined together at noon, and adjourned at four o clock

THE FOURTH DISTRICT BRANCH

The first District Branch to hold a meeting this fall was the Fourth, which met in Saratoga Springs on Thursday and Friday, September 19-20 The program began in the Auditorium of the Y M C A with a general meeting addressed by the Hon Bernard M Baruch, who described the objectives of the Saratoga Springs Commission of the State of New York as follows according to a news release in the New York *Times*

It is estimated that over 100 000 Americans go abroad annually to the cures Their expenditures is estimated at not less than $100 - 000,000 All these do not represent the people who go abroad to take the cures similar to Saratoga's but a large percentage of them are This is not important by itself but only as being indicative of the fact that there must be many more hundreds of thousands of Americans who are unable to go abroad and it is this larger number who have not the means to seek relief in Europe that the State should have particularly in mind

'I shall recommend to my commission the establishment here of not alone the proper bathing facilities, but of the famous mud baths If we cannot find the proper mud we can easily import it, because keeping the mud for the time of transportation would improve it

'I think further we should have the 'Gradeur' bath which is being used abroad for bronchial troubles And as we are able to develop under scientific assistance, we should have a complete Zander institute, heliotherapy generally known as sun baths and all of the forms of physiotherapy used under the most careful medical and scientific supervision

'I feel that the State should maintain here a research laboratory to which could be gathered information not alone from our own clinical studies but data gathered in cooperation with European institutions I have already made arrangements for a gathering of the recorded knowledge that is being obtained there as a result of their experience and study

'It is my hope that we will be able to bring to America the latest views and the best equipped individuals to help us carry out to the fullest extent the development of the bath

Mr J G Jones Superintendent of the Saratoga Springs Reservation showed moving pictures of the therapeutic application of the waters A special trip through the Reservation was then made in automobiles loaned by citizens, ending with an inspection of the new Lincoln Baths erected at a cost of $775,000 Most of the visiting doctors were surprised at the area of the Reservation, and the extent to which the baths were used

In the evening Dr James E Sadlier Chairman of the Committee on Public Relations, held a conference with the chairmen of the Public Relations Committees of the several counties of the District, and explained to them the objects of the committees and their methods of work He especially called attention to the extensive reports of the work of the committees appearing in the State Journal, and urged all county chairmen to look in the news section of each issue of the Journal for official reports of not only his committee but of all the other committees and officers of the State Society

A supper was served in the Masonic Building in the evening after which the officers of the State Society were introduced

President J N Vander Veer spoke on the current work of the State Medical Society, dwelling especially on the following activities

1 Nursing Service, and the need of practical attendants to care for patients in the sick rooms at home

2 The cost of medical attendance, bringing out the fact that doctors fees constitute only a small proportion of the entire expense of sickness and that luxuries constitute the greater part of the expense

3 Post-Graduate courses, explaining that the instructors sent out by the State Medical Society get little remuneration for their services, and that each one loses a day's work, it was therefore the duty of the members to patronize these lectures

4 The relations of physicians to the State Departments of Health These are now satisfactory and it is the aim of the State officers to establish equally satisfactory relations with the lay health organizations

5 Publicity of County Society work A county can advertise itself in the newspapers, while individual doctors can not The Journal is open for reports of the county society meetings and activities These should be reported for the encouragement of other county societies

6 A plea that the members will read the news department of the Journal for there they will find records of the activities of the officers

an extent that the Board of Supervisors asks for the opinion of the medical society in health matters The doctors are no longer being led, but they are leading in civic health affairs They are working in harmony with lay health organizations, and the County Council on Social Organizations has asked the medical society what health program would be practical in the county "Periodic Health Examination" was chosen and plans have been made to put on a campaign in which the Mayor of Utica and the members of the Board of Supervisors will be examined first The County Medical Society was also joining the lay organizations in an extensive series of advertisements of the examinations

Dr Dougherty called attention to the full-page advertisement in the New York *Times* of Sunday, August 18th, which was inserted under the joint auspices of the five county societies of Greater New York, and four of the leading voluntary health organizations of the state This advertisement called attention to the value of periodic health examination (See an editorial in this Journal of September 1, 1929, page 1079)

Dr Matthias Nicoll, Jr, State Commissioner of Health addressed the Conference on the plans of the Committee on the Cost of Medical Care, as sponsored by the American Medical Association, and other organizations, both medical and lay He said that the State Department of Health has been asked to cooperate in securing data from three thousand families in villages of five thousand inhabitants or less The investigation will include the amount spent for physicians, for medicine, for patent medicines for chiropractors, and for hospitals and other expenses The method suggested would be that the public health nurses should do the work, visiting families about every two months

Dr Nicoll said that he would present the subject at a conference of the District Health Officers to be called soon, and asked that a representative of the State Medical Society be present to give advice from the standpoint of practicing physicians He called attention to the survey of morbidity made by one hundred doctors who sent weekly reports of the cases of sickness to which they were called This was the first extensive survey of the practice of average physicians

Dr Nicoll praised the doctors for their response to the questions on maternal deaths that had occurred as a result of childbirth, a questionnaire having been sent to every doctor having such a death

The sentiment of the Secretaries was in favor of Dr Nicoll's plans

Dr J N Vander Veer gave a practical talk on the activities of the State Society and mentioned the number of inquiries which County Secretaries make to the State Society, many of which the Secretaries could answer for themselves by reference to the Directory, the Journal, or other publications that are sent out by the State Society He called especial attention to the publications, copies of which were distributed to each person present including the Constitution and By-laws of the State Society, its Principles of Professional Conduct, the Workmen's Compensation Law, The Medical Practice Act, and the law relating to the Care of Crippled Children He suggested that every secretary have copies of these and of other laws on file for reference

Dr Vander Veer called special attention to the Workmen's Compensation Law, and said that if doctors would follow its provisions, they would receive their money promptly (See Dr Vander Veer's article in this Journal of April 1, 1929, page 395)

Dr Vander Veer also mentioned Fee bill prepared by the Committee on Public Relations for the Medical Care of Physically Handicapped Children (See this Journal of February 1, 1929, page 171) He said that another fee list had just been published by the Adjutant General of New York State to cover the medical treatment of National Guardsmen when on duty Physicians must expect fee lists to be prepared for the use of officials who deal with the bills of doctors in private practice

Dr Vander Veer called attention to the Special Committee on Periodic Examination, of which Dr C Ward Crampton of New York, is Chairman Albany County will put on a Health Week during the third week of November, and he urged other county societies to form active committees on Public Relations in order to lead and direct such movements as these

Dr W H Ross, President-elect of the State Society, read some reflections which had occurred to him while he listened to the addresses at the Conference The majority of the doctors, he said practice curative medicine as their major work and preventive medicine as a minor activity The first duty of a doctor is to support himself and his family, and lay up a competence for old age This he must do principally by the practice of curative medicine County Medical Societies will be interesting when they teach doctors to practice better medicine The people are making demands on the doctors for new forms of service We will strengthen our position by heeding the demands of the people and by recognizing the good which the voluntary health organizations are seeking to do, and correcting their forms of doing it Don't criticize their whole program, but attack only their errors

Dr T P Farmer, Chairman of the Committee on Public Health and Medical Education, said that preventive medicine depends on adequate medical care and on procedures, such as the administration of anti-toxin which can be done only by doctors The Committee is seeking to give the doctors courses of a practical nature which will enable them to do better practice

The meeting was characterized by a deep interest in the proceedings and by a cordiality among the doctors present The program was brief and pointed The assembly room was large, comfortable, warm, and well-lighted, and a dinner was served in the same room by waiters who prepared the tables quietly while the regular program was going on The coziness of the room and the perfection of the arrangements contributed much to the success of the gathering

The meeting began with a conference which was not listed on the program Dr J E Sadler, Chairman of the State Committee on Public Relations, had planned to call together the Chairmen of the Committees of the several counties at each District Branch Every chairman of the Third District Branch had responded The conference was held in one corner of the general meeting room and other physicians dropped in joined it and listened interestedly to the reports from the counties thereby gaining a new insight into the problems which exist in every county society in regard to the relation of physicians to other agents practicing some form of medicine in the county

The Chairman of Rensselaer County presented a detailed survey of the medical service in his county This will be printed in an early issue of the Journal

The first number of the formal program was a paper entitled "The Medical ProfessionEconomically Speaking," by Dr Shirley W Wynne, Commissioner of Health of New York City Dr Wynne brought a formal paper, but seeing the friendliness of the members present, he gave an informal talk which was much more effective than a formal paper would have been Dr Wynne gave an intimate talk, which was almost confidential, on the relations of the New York City Department of Health to practicing physicians While the Department of Health he said, was well organized to carry on the various activities which belong to a Health Department the five county societies were not well organized for the purpose of carrying on the activities of preventive medicine which properly belong to physicians whether individually, or as groups, in their own county societies As examples of fields of preventive medicine long neglected by physicians Dr Wynne mentioned diphtheria antitoxin known for thirty years, but not universally used by doctors in a preventive way school children present an immense number of defects, but only a comparatively small proportion of them are corrected by family physicians nearly every doctor has tuberculous cases on his calling list but it too frequently happens that the doctor treats his cases for a year or more simply by giving medicines by mouth Doctors are prone to leave preventive medicine work to official health departments and to lay health agencies The pedtricians form a group which is an exception to the general rule, for the greater part of their work is to keep well babies well

The City Department of Health is almost compelled to conduct clinics for treating cases, but its policy is to send cases to family doctors for treatment, and to conduct clinics for the purposes of diagnosis and education only The City Department of Health will continue to conduct diagnostic clinics in order to provide free laboratory tests for the benefit of the doctors, but the Department will close its treatment clinic as fast as the doctors will give the treatments, and the Department of Health will send its nurses to assist the doctor in the treatment of his private cases which were formerly treated in the clinics

Consider the unpreparedness of the physicians at the present time If Johnny Smith comes home from school bringing a letter from his teacher that he should have toxin antitoxin, what does the family physician do? He may have no toxin antitoxin on hand, or his hypodermic syringe is out of order, or he has no needle for it, and so he says— Go to the Health Department Clinic where you can get the tretament free" If the doctors would take a lesson from business men they would devise a plan by which each doctor can organize his office so as to give the treatments He will arrange, for example, to give toxin antitoxin on Saturday mornings, and will have his nurse or helper in attendance and will give say twenty treatments in a morning But no county society has put forth such a plan

The public wants the benefit of real preventive medicine, and will get it from some source, preferably from the doctors, but from other agencies, if the doctors do not give it The trouble and interference which the doctors anticipate are not actually from the outside but are in themselves Let them face their own defects, and organize to distribute their services, join with the Health Departments and cooperate with the Department's plan that the family doctors shall give treatments for conditions which are diagnosed by the Health Department If the doctors and the Health Departments get together there will be an end of State Medicine

Dr Arthur D Benson, President of the Rensselaer County Medical Society continued a discussion of the points brought out by Dr Wynne and introduced the following resolution

Resolved That the Third District Branch of the New York State Medical Society recommend the innoculation of pre-school and school children for the prevention of diphtheria,

That health organizations and departments more actively educate the adult population of communities as to the need, method and results (including limitations) of diphtheria immunization,

That these organizations and departments sincerely recommend the family physician to

and committeemen of the Society, and recommendations to the county societies

The President-elect, Dr W H Ross spoke on "Definiteness of Purpose of County Societies" The doctors should know the peculiar field of the work of the medical profession, of the official State Departments of Health, and of lay organizations, for each group has its own necessary work Let the doctors stop obstructing the work of lay organizations, but learn what their peculiar field is, and help them in the discharges of these duties

Dr J E Sadlier, a Past-President, and now Chairman of the Public Relations Committee, followed up the thought of Dr Ross and called attention to the great progress made by some counties in the relations of their doctors to other health groups, and said that what a few counties have done the rest could do

Dr John A Card, Chairman of the Special Committee on Group Insurance, explained the system of indemnity insurance adopted by the Medical Society of the State of New York, and said that this insurance was cheaper than that offered by any other company, and far to be preferred to that of companies which had no right to do business in New York State He said that three hundred suits against doctors had been instituted in New York State during the last year, and he warned the doctors that anyone present may be the next one to be sued

The principal speaker of the evening was Dr Francis R Packard of Philadelphia, who gave a description of the work of Ambrose Pare the famous French surgeon, who was born in 1510 and died in 1590, and was honored as the physician to the Kings of France He was of lowly origin and had no education in Latin In his time physicians were divided into three groups, the first group those licensed by the College of Physicians where the instruction was in Latin It was beneath the dignity of these men to do operations of any kind The second group was composed of surgeons of the "long robe" alluding to the long cloak which they wore These were licensed by the physicians, but they knew little and were the assistants to the physicians The third group were the barber surgeons, who did all the practical surgery These were licensed to do operations only, the principal ones of which were amputations and lithotomies When Pare began his career in Paris in 1532, he was not even a barber surgeon but simply an assistant or interne in the Hotel Dieu But he learned from everybody Beginning in 1536 he spent two years with a regiment in an Italian Campaign, and there came in contact with all sorts of wounds of soldiers His experience and skill as a military surgeon gained for him a license to practice as a Barber Surgeon His skill came to the notice of the King, and he was made a surgeon of the "Long Robe" by direct order of the King Pare was noted for introducing six items of progress in surgery

1 Ligation of arteries after amputations in place of cautery
2 The use of ointments and soothing applications for gun-shot wounds in place of filling them with boiling oil
3 The invention of the artery clamp
4 Podallic version in child-birth
5 The recognition of metastatic abscess following purulent wounds
6 Writing medical books in French which would be comprehensible to the barber surgeons of his day

The address of Dr Packard was of thrilling interest and was illustrated with lantern slides

The District Branch held a morning session on Friday, September 20, at ten o'clock The first number on the program was "Child Welfare Survey of Saratoga County," by Dr J R McElroy of Jonesville This paper is an amplification of a report which appeared on page 104 of this Journal of January 15 1929, and will be published in an early issue of this Journal

Dr Leo F Schift of Plattsburg, gave a paper on "The Diabetic in General Practice"

Periodic Health Examinations were described by Dr C Ward Crampton, Chairman of the Special Committee on Periodic Health Examinations of the Medical Society of the State of New York Dr Crampton described the salient features of the work which his committee expected to accomplish at its organization meeting in the afternoon A report of this committee will appear in an early issue of the Journal

The guest of the meeting was Dr Frank H Lahey, of Boston Mass whose subject was "Gastric and Duodenal Ulcer" Dr Lahey spoke for an hour in a simple, clear way which thrilled the audience He ended with a series of lantern slides illustrating the various conditions of the ulcer and methods of treatment

THIRD DISTRICT BRANCH

The second meeting of District Branches to be held this fall was that of the Third District Branch, comprising the seven counties of Albany, Rensselaer, Schoharie, Greene, Columbia, Ulster and Sullivan About seventy-five doctors were present

mittee by the Executive Committee of the Council were formulated, and will be reported upon at the next meeting Members should watch for this report

A meeting of the chairman of the Public Relations Committees of the county societies was discussed It was decided that conferences of the committees should be called in connection with the meetings of the District Branches The object of the District Conferences is to discuss the relations in each county between the medical profession and other organizations, both lay and official, whose activities have a bearing on health A further object is to explain the plans and standards of the State Committee on Public Relations The State Committee anticipates an expansion of interest, an increase in publicity, and a forward step in mutual cooperation as the result of this economical plan of conference

The chief present activity of the Public Relations Committee of each County is to take the fundamental step of making a survey of existing health organizations and their functional activity in preventive medicine, and of the hospital and welfare facilities in the County, and following this, a study of the present relationship of medicine to all these organizations

Plans were advanced, but not fully matured, regarding methods of cooperation with lay health organizations, and with fraternal, welfare, educational and commercial societies in their health programs

The State Public Relations Committee offered to the Committee on Economics the services of the County Society Public Relations Committees in County Societies not having a Committee on Economics, for the purpose of assisting the Committee on Economics in gathering information in its studies on the compensation law

The Public Relations Committee will attempt this year to find the basic principles of relationship which exist between the medical profession and other health agencies, and will also attempt to advance the study of basic problems of medicine, with no illusions as to the difficulty or seriousness of the task

This report is made as complete in detail as space in the Journal permits and as concise as the Committee thinks it should be in order to be read digested, and put to use by the profession It illustrates the work that the officers of the State Society are doing in the interest of the entire profession of medicine—and it hopes that the members may comment upon it either to the Chairman, Dr Sadler in Poughkeepsie, or the Secretary, Dr Ross in Brentwood

W H Ross, *Secretary*

give these injections, while providing the necessary facilities when a family cannot afford a private physician,

That physicians and clinics, etc, be required to report to the Health Board all cases innoculated

That a record be kept by the Health Board of all cases innoculated

That a suitable certificate of injection be sent to parents by the Health Board

The second number on the program was a paper by Dr George F Chandler, of Kingston, on the topic "America Practices Medicine" Dr Chandler contrasted the European, or mass, method of the practice of medicine with the American, or individual plan The European plan could never be transported to American soil, for American citizens demand individual treatment

The third number on the program was an address on "Periodic Health Examinations," by Dr C Ward Crampton of New York, Chairman of the State Committee on Periodic Health Examinations Dr Crampton explained that doctors face a new epoch, whereas they had been seeing pathology in its X Y Z, or end results, they will see its A B C, or begining, in the future Recognize and correct the pathological in its early, or pre-clinical stage, and the physician will increase the efficiency of the citizens, and the race Dr Crampton said he had no illusions regarding the immediate application of the plans of the committee on Periodic Health Examinations, but that five years from now he expected physicians generally to take a deep interest in making examinations of well people and advising them how to keep well Pediatricians have set the example by their advice to children There is no reason why the same system cannot be extended to grown people with almost equally good results

Addresses by the officers of the Medical Society of the State of New York were scheduled on an "after-dinner program

Dr James N Vander Veer, President of the State Society, explained some of the major activities which the Society is now carrying on, and stressed the value of the New York State Journal of Medicine in recording those activities The Journal, he said, is the official organ of the Society and contains news of what the County Societies are doing, and it is the duty of every physician, especially those holding office in the State and County Societies, to read the news department of the Journal in order to learn what the organized profession is doing

Dr W H Ross, President-elect, called attention to the very great progress which has taken place in the practice of medicine by medical societies in New York State during the last five years He said that the activities of the Committees, such as that on Medical Economics, had started when the Society got money to pay the expenses of the Committees The Trustees of the State Society decide if an activity is of real value, and appropriates money to carry on

Dr John Card, Speaker of the House of Delegates, described the method of defense in malpractice suits, and warned general practitioners and specialists that they need protection as well as the surgeons (See page 1216)

Dr D S Dougherty, Secretary of the Medical Society of the State of New York, emphasized some of the points which had been brought out by Dr Wynne He spoke of the increasing relations of cordiality developing between the Health Departments and the physicians, and said that evidence of the increasing cooperation by the doctors was the fact that 50% of the reported immunizations against diphtheria have been done by family physicians Physicians are now getting together with the lay-organizations in the same way that they have with the official Departments of Health

COMMITTEE ON PUBLIC RELATIONS

The Public Relations Committee of the Medical Society of the State of New York held its first meeting of the year at Albany, September 11th, from ten o'clock until three, with a full attendance of all its members—J E Sadlier, Chairman, W H Ross, Secretary, W D Johnson, A J Hambrook, O W H Mitchell, and President James N Vander Veer, ex officio Its personnel and its officers remain as they were last year

Drs Sadlier and Ross were appointed a Committee to confer with the Departments of Health and of Education regarding the care of crippled children and the compensation of physicians for professional services

It was reported that forty-five county societies have Public Relations Committees, but only eight societies have made reports of the various forms of health activities conducted in their counties Surveys from the other counties will be expected this year

State aid in general hospital buildings, including their equipment, maintenance, and administration, was carefully considered Drs Sadlier and Ross will confer with the State Department of Health on this subject, Dr Johnson will undertake to obtain the opinion of the Medical Society of the County of Wyoming in reference to it, and the general subject will be continued at the next meeting of the Committee

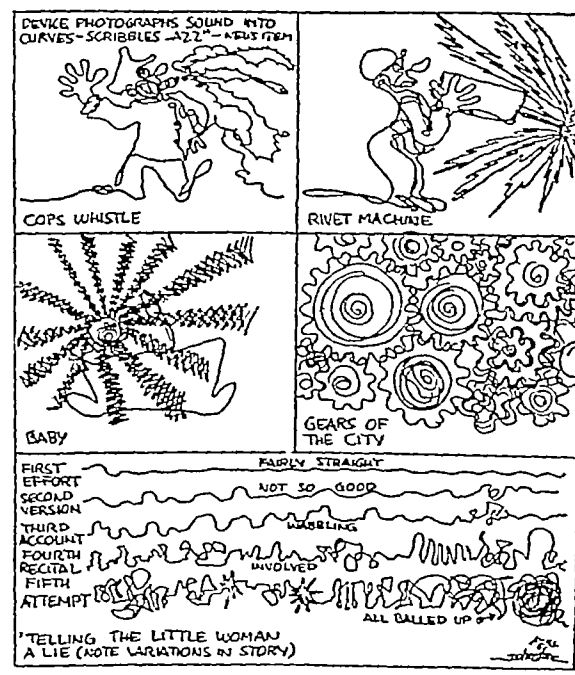
Methods of administration to carry out several resolutions originating in the House of Delegates and referred to the Public Relations Com-

THE DAILY PRESS

NOISE AND HEALTH

IT is often said that noise is irritating, and that silence is oppressive The New York *Herald Tribune* of September 18 quotes Dr Samuel A Brown, Dean of Cornell Medical College, as saying that two major health menaces of New York City are noise and carbon monoxide Concerning noise Dr Brown is quoted

'If the city noises continue to grow, it will be a physical impossibility for people to live in the city," he said "These disturbing sounds persist for twenty-four hours Although people think they get away from them when they sleep the effect upon the nervous system is not different from what it is when they are awake



'Definite legislation must be created to meet this situation There is no mistake about that The sooner it comes the better Thousands of persons are having their health broken each year as a result of city sounds and there is no reason why the societies to suppress sounds should not have nation-wide co-operation in getting corrective legislation

"One is oblivious to noises only because of mental control The harrassing effect does not change We are still susceptible, much as we say we have grown used to the nuisance"

The diagnosis of the elements of noise is not so simple as one may think One scientist spent days measuring the intensity of various kinds of noise in the city, and came to the conclusion that the most intense was that of trains on the elevated railroads

No one can say what sounds are the most irritating and therefore, presumably, harmful The sound of a water faucet dripping a drop every ten seconds in the middle of the night produces one of the most annoying of all noises, but we become accustomed to loud noises which are continuous Yet there are deaf people who can hear well in the subway din which deafens those with normal hearing There are also those who believe in the innate unhealthfulness of any noise, and these persons have formed themselves into an anti-noise society as described in this Journal of July 1, page 839

To ourselves the noise that is the most annoying and noisy is the rasping voice and giggling of a flashy flapper on a smoking car when we are searching the morning paper for material for the department of the Daily Press But we are reminded of the boy's remark that It is no fun to play if you can't make a noise!"

Graphic representations of various well-known noises interpreted by an impressionable artist, in the New York World of September 19, 1929

THE SARATOGA SPRINGS STATE PARK

The meeting of the Fourth District Branch of the Medical Society of the State of New York at Saratoga Springs on September 19 and 20 was widely noticed in the daily papers, especially that part of the program relating to the development of the State Reservation The New York *Times* of September says editorially

"Mr Bernard M Baruch now devoting himself to the rehabilitation of Saratoga Springs under a commission from Governor Roosevelt, returns from a tour of foreign watering places in the confirmed belief that Saratoga is as good as the best of them He wants the medical fraternity to cooperate with the authorities and send their patients there

BOOK REVIEWS

RECENT ADVANCES IN SURGERY By W HENEAGE OGILVIE, M.A., M.D 12mo of 461 pages, illustrated Philadelphia, P Blakiston's Son & Company, 1928 Cloth, $3.50 (Recent Advance Series)

This book of 461 pages with 108 illustrations concerns itself with the proven advances made in general surgery This does not mean that the text of the work depicts any thing brilliantly new or phenomenal. By the time a new procedure has proven its value, it is already old. However, in its 16 chapters the author and his collaborators have sifted out of the mass of newer things surgical in nature, the ones which have proven to be of value and of constructive interest.

To enumerate the individual advances found in the book would require a complete paraphrase. Suffice it to say that the reviewer has found it well worth his while reading its contents He recommends it to all those interested in surgery

MERRILL N FOOTE.

A MANUAL OF DISEASES OF THE NOSE, THROAT, AND EAR. By E. B GLEASON, M D Sixth Edition. 12mo of 617 pages, illustrated. Philadelphia and London, W B Saunders Company, 1929 Cloth, $4 50

This text book of handy size, which was originally printed in 1907 and has been revised and rewritten many times, is exceptional. It is exceptional because of its thoroughness and the comprehensive plan which the author has followed.

Although intended for the student and practitioner, this book may well be studied by the otolaryngologist, for its contents represent the fundamentals of the specialty In so fine a text-book as this it is disappointing to find space given to paraffin injection for nasal deformities.

The section on the ear is especially to be commended particularly that portion which deals with the internal ear

For its size the book is unusual for its completeness and lucid style. M. C M.

THE NORMAL AND PATHOLOGICAL PHYSIOLOGY OF BONE. Its Problems By R. LERICHE and A. POLICARD Authorized translation by SHERWOOD MOORE, M.D, and J ALBERT KEY, M.D Octavo of 236 pages, illustrated. St. Louis, The C. V Mosby Company, 1928. Cloth, $5 00

Of necessity much of the finer colorings of expression are lost in translations but Drs Moore and Keys are to be congratulated on the fullness of this translation. "Physiology of bone" is not adapted to the junior student because of the very frankness of the authors, but for the senior medical student or the resident physician it is most excellent as it puts before him in a clear concise manner the true status of the present knowledge of the physiology of bone and clears away much of the dead wood that has come down to us from past generations The chapters on the repair of fractures and bone transplantation is of great value to the bone surgeon.

The entire work is stimulating and should lead to more research work on the physiology of bone. The observations upon which the conclusion of the authors are based are founded on years of study and much of it came from their study of bone injuries during the great war We feel that this book is an original contribution to the study of bone of great value.

J C. RUSHMORE.

OLD AGE THE MAJOR INVOLUTION The Physiology and Pathology of the Aging Process By ALFRED SCOTT WARTHIN, Ph D., M.D Octavo of 199 pages, illustrated New York, Paul B Hoeber, Inc., 1929 Cloth, $3 00

This volume is an elaboration of the author's Wesley M Carpenter Lecture of the New York Academy of Medicine under the title, "The Pathology of the Aging Process" It is a scholarly presentation of a somewhat sentimental and idealized subject—old age—and the volume will well repay a careful study

Instead of being depressed by the ultimate outcome of living, the author offers "a rational workable philosophy of Old Age as an antidote to the modern futilities of life—extension of the individual to extreme limits and of possible rejuvenation." He feels that "today the scientific mind may obtain satisfaction and happiness in the contemplation of the potentialities of the mortal individual in carrying on and advancing the immortal potentiality of the germ plasm" In a masterful manner, the author pictures the human machine through the periods of youth, of maturity and of old age as a logical sequence with functions of each period considered.

In closing, the writer states "Happy then is the senescent who can approach his inevitable end with a normal rate of involution, still capable of intellectual pleasures, and the mature contemplation thereof, to meet a speedy release before the unhappy days of second childhood are upon him."

This is a masterpiece.

HENRY M MOSES

PHYSIO-THERAPY IN GENERAL PRACTICE AND FOR THE USE OF MASSEUSES By E. BELLIS CLAYTON, M.B, B Ch. Second Edition Octavo of 231 pages New York, William Wood & Company, 1928 Cloth, $3 50

This volume presents in a concise and interesting manner a rather complete exposition of physical therapy Extreme technical detail of the electrical modalities is avoided, but their uses are well covered. Several excellent chapters are devoted to diseases of the nervous system and their treatment by physical measures The chapters dealing with corrective exercise are particularly valuable.

The book is very well illustrated, which constitutes a great help in the description of the rather involved exercises upon which the author depends for his success in treating certain deformities. It is well written and clearly printed, and can be recommended for the use of the physical therapy aide as well as the student and practitioner

JEROME WEISS

HANDBOOK OF SURGICAL DIAGNOSIS By CLEMENT E. SHATTOCK, M D 12mo of 678 pages, illustrated. New York, William Wood & Company, 1929 Cloth, $5.50

This book contains 678 pages with 78 x-ray photographs It is purely clinical in nature and has as its object the presentation of the differential diagnosis of the commoner surgical affections The morbid anatomy of many of the diseases under discussion is included. The more important complications of some of the conditions have been enumerated.

The book will find its greatest use in the hands of students and the practitioner who may be called upon to make a differential diagnosis at times when it would be not feasible to go into the disease in great detail. The reviewer feels that because of the subject matter and because of its presentation, the book will serve a very useful and real purpose.

MERRILL N FOOTE.

' For years one of the chief obstacles to the development of Saratoga has been mental The curative properties of its waters, especially in cardiac troubles, have been widely recognized But most patients bidden to take the cure prefer to combine it with a trip to Europe They think that there is some magic about the waters of Homburg or Nauheim or Aix that our own springs cannot command

"Here is an exception to the rule of pride in native superiority One would expect a 100-per-cent American to greet a European physician's prescription of his baths in much the spirit Naaman the Syrian replied to Elisha's suggestion that he cure himself of the leprosy by bathing seven times in the River Jordan

"Are not Abana and Pharpar, rivers of Damascus better than all the waters of Israel? May I not wash in them, and be clean?"

RAISING WHITE MICE

White mice are saviors of human life, for those living in cages under the vigilant eyes of watchful scientists reveal health secrets of mankind as well as those of their own race The New York Sun of September 18 has the following article description of a breeder of the animals

"Add to the list of interesting occupations—David Mayer, white mice breeder Definitely this New Yorker contributes to the public health Without him the United Public Health Service, the New York City Board of Health, the various experimental laboratories and the hospitals would be seriously inconvenienced After all, it is not possible to go out and catch a white mouse whenever you happen to need one

"David Mayer has been breeding white mice for thirty years for research purposes, and in that long time has supplied more than 45,000,000 to the laboratories, the medical schools and the various health services the country over He began his odd vocation a generation ago with just ten pairs, which goes to show what a good man can do if he has the right idea In the whole country he has only two competitors of note in the white mice breeding business—one in Philadelphia and one in Kansas

"His work and business have grown apace with the development of research and a better understanding on the part of the public as to what laboratory experiment has to do with public health He himself says that he is a student in genetics His white mice have helped the United States Army doctors solve yellow fever problems in the Panama Canal Zone and in the Philippines, have done their part toward conquering plagues of all kinds and have been simply invaluable in the persistent and determined effort to conquer one of Mankind's greatest scourges—cancer

' David Mayer's shop, the headquarters of a unique and invaluable industry, is in Eighth Avenue between Thirty-third and Thirty-fourth streets You are likely any time you go into the place to encounter a scientist of world fame Mr Mayer knows probably more savants, with alphabetical disarrangements after their names than any other man in New York, outside of a limited group of scientific repute themselves"

TELEPHONE BOOKS

Numbers are notoriously difficult to print clearly and legibly, especially when immense volumes of figures must be printed cheaply, such as telephone books The *New York Times* discusses the legibility of printed numerals on its editorial page of August 22 as follows

"A study of illegibilities in numerals has been made in the department of psychology of the Ohio State University The results of a survey of 135,371 numerals written by 1,127 persons have been embodied in a report for the American Association for the Advancement of Science

"Among the specimens studied were bank checks, luggage checks and sales slips The numeral 5 was found to be the black sheep of the family It furnished 46 per cent of the total illegibilities In almost half of the cases the difficulty was due to the incorrect placing of the dash at the top Zero came next with 13 per cent of the inaccuracies

"Next on the list of offenders, especially with children, were 7 and 2 The ornamental tick at the beginning of each causes the trouble in this case

"Difficulties in understanding numbers over the telephone have been decreased by changing five to fi-vuh, three to thrrrree, &c. The clearness of written numerals might be helped by in some way exaggerating the refractory ones The French have tried that method by branding their 7 with a short cross mark"

The only effective way of securing legibility of the telephone book is to spend more money for clear type, smooth paper, and better printing

CLINICAL ELECTROCARDIOGRAMS Their Interpretation and Significance. By FREDERICK A. WILLIUS, B.S., M.D. Quarto of 219 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1929. Cloth, $8.00. (Mayo Clinic Monographs.)

The text of the book is devoted entirely to the reading of the records and their clinical significance without discussion of the technic of electrocardiography, preparation of records or theory. A full bibliography adds to its value. Each record, of which there are 368, is accompanied by an interpretation.

After a brief description of the normal electrocardiogram, the waves are described. The term "ventricular preponderance" is still used, apparently in preference to "axis deviation."

In describing bundle-branch block a distinction is made between incomplete and complete, following the work of Wilson and Herrmann. The incomplete form produces changes which are transitional between the normal ventricular complex and the complexes characteristic of complete bundle-branch block, that is, less amplitude of the deflection of the QRS, less duration of the QRS and frequently less notching of the components of the same. The author agrees that it is sometimes difficult to decide between these forms.

Increased amplitude, or notching of the P wave or inversion of it in lead 3 alone, are not believed to have any definite significance. T wave negatively in lead 1, in leads 1 and 2 and in leads 1, 2 and 3 combined is of the greatest importance, whereas that which occurs in leads 2 and 3, is important, but to a lesser degree. The author has previously published mortality tables about this, which are presented here. The prognostic importance of low voltage waves is considered uncertain. The T waves of coronary thrombosis are described and illustrated.

The book is a valuable addition to the literature of electrocardiography.

W. E. MCCOLLOM

THE TOXEMIAS OF PREGNANCY. H. J. STANDER. Octavo of 161 pages. Baltimore, The Williams & Wilkins Company, 1929. Cloth, $3.00. (Medicine Monograph No. XV.)

Stander's book is a compilation of modern ideas of the toxemias of pregnancy with an excellent bibliography. All his own research of the last few years is included, and a strong argument is presented for the well known Johns Hopkins classification, which seems to be an admirable one. The question of hypo or hyperglycemia still seems to be open, and no new material is brought out. It may well be that the metabolism of Glucose is such a complicated question that whether there is an excess of sugar in the blood or not is of little importance. Perhaps too much space is allotted to discussion of the time-worn theories of etiology. Treatment is conservative on the basis of our clinical experience of the last thirty years. The book is compact, well done, very readable, and the story well told.

C. A. G.

NOTES ON CHRONIC OTORRHOEA. With Especial Reference to the Use of Zinc Ionization in the Treatment of Selected Cases. By A. R. FRIEL, M.A., M.D. Octavo of 87 pages, illustrated. New York, William Wood & Company, 1929. Cloth, $2.25.

Chronic otorrhea is one subject in otology that is often a puzzle to the otologist. Can a discharge that has been present for years be stopped? In trying to stop it, what treatment is indicated? Is an operation necessary, and if so, will it be a simple or a major one? The author does not attempt to answer all of these questions. He discusses only one method of treatment—ionization.

In the first part of the work he describes the principle of ionization and the instruments necessary for this treatment. The second part is devoted to treatment. Not only is the technic of ionization given, but the selection of suitable cases is discussed. The preparation of a case for ionization by enlargement of a perforation, removal of polyps, a portion of the drum or outer attic wall and proper cleansing of the ear are all carefully considered. At the end of this part are a number of tables showing the result of this treatment from the work of others as well as that of the author.

The ten pages in Part Three are devoted to the organization and conduction of an aural clinic. It must be remembered that the author is working in an English clinic, and some of the methods of organization will not apply to a clinic in an American city, but from this part of the work, any one conducting any clinic can get suggestions that will conserve his time and enable him to render his patients better treatment.

The work is a small one, only eighty-seven pages, is well written and should be read by every otologist.

JOHN W. DURKEE.

RECENT ADVANCES IN NEUROLOGY. By W. RUSSELL BRAIN, M.A., D.M., and E. B. STRAUSS, B.A., B.M., B.Ch. 12mo of 412 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, 1929. Cloth, $3.50. (Recent Advances Series.)

The authors of this book will merit the commendation of all who become acquainted with the contents of its material. The book brings one directly into the forefront of neurologic advancement without having to wade through the thick underbrush of elementals and generalities found in most books on neurology. It is evident at the same time that the authors intended to accentuate and illuminate fundamental principles of neurology and biology by clarifying moot questions and difficult problems in the light of our present knowledge. This book is essentially a treatise on recent advances in clinical understanding and therapeutic measures. It includes also data on neuro-surgery. Each chapter has appended to it a resume of recent references on the subjects dealt with.

The authors seem to be committed to the psychology based upon Pavlov's Conditioned Reflex theories, for Freud and his followers and their prolific contributions to dynamic psychology are nowhere mentioned in the book. However, since this is the only chapter on functional neurology and deals in the main with Pavlov's work, one may look upon this grave deletion as purposive in order to keep strictly within the bounds of what is new in neurologic literature. Otherwise there is little else to wish for in a small book such as this is that could be more stimulating and refreshing in character.

SIMON ROTHENBERG.

HEMORRHOIDS Their Etiology, Prophylaxis and Treatment by Means of Injections. By ARTHUR S. MORLEY, F.R.C.S., Eng. Fourth Impression. Octavo of 122 pages, illustrated. New York, Oxford University Press, 1929. Cloth, $2.00. (Oxford Medical Publications.)

Writing from an experience of more than 3500 cases the author may well be called the father of the present day injection treatment of hemorrhoids.

His book is all that such a monograph should be. It is carefully written, well illustrated and printed and covers every detail of the subject.

It is the "reference book" for the injection of hemorrhoids.

This edition describes in detail a modified treatment now used by the Author.

HENRY F. GRAHAM

A PATIENT'S MANUAL OF DIABETES. By HERBERT W. MOXON, B.A., M.R.C.S. 12mo of 132 pages. New York, William Wood & Company, 1929. Cloth, $2.25.

This is a well-written manual, brief and clear, which does not have much to add to the dozen published books dealing with the same subject. A few illustrations might have made it somewhat more practical for the patient.

WILLIAM S. COLLENS

EDEMA AND ITS TREATMENT By HERMAN ELWYN, M D Octavo of 182 pages New York, The Macmillan Company, 1929 Cloth, $2 50

The problem of edema is one upon which there has been much discussion and there is still much room for discussion The author in this volume has most clearly presented his point of view that we are "dealing with a physiological organism in which there are always adaptive regulatory mechanisms which have been developed phylogenetically"

The author has presented in a scholarly manner the many theories concerning edema and from these, together with his own studies, has given an excellent view of the subject. He explains the edema of cardiac failure, of glomerulo-nephritis, of lipoid nephrosis, of chronic undernutrition, and edema of obscure origin He gives in addition a chapter on the treatment of edema.

This volume is a carefully written book and is most valuable in the studies relating to these conditions leading to edema. It is well worth much study by the physician.

HENRY M MOSES

PROCTOLOGY A Treatise on the Malformations, Injuries and Diseases of the Rectum, Anus and Pelvic Colon By FRANK C YEOMANS, A.B, M D, F A.C S Octavo of 661 pages, illustrated New York and London, D Appleton & Company, 1929 Cloth, $12 00

The author was an associate of Dr James P Tuttle and this volume will assume the place long occupied by the standard Treatise written by Dr Tuttle on Diseases of the Anus, Rectum and Pelvic Colon

The paper, type, illustrations, 417 in number, the 4 colored plates and the general arrangement of the book are excellent. The literary style is marked by simplicity, absence of unnecessary verbiage and freedom from obsolete and useless material

All the latest methods of treatment are discussed such as radium, carbon dioxide snow, diathermy, spinal anesthesia, injection treatment of hemorrhoids and new methods devised by the author for the treatment of pruritus ani and other diseases

A detailed description of the various chapters of this book cannot be given. Suffice it to say that it thoroughly covers the field indicated by its title. The Reviewer has spent many interesting and profitable hours browsing among its pages and can heartily recommend it to others

HENRY F GRAHAM

TWEEDY'S PRACTICAL OBSTETRICS Edited and largely rewritten by BETHEL SOLOMONS, M D Sixth Edition. Octavo of 759 pages, illustrated New York, Oxford University Press 1929 Cloth, $7 50 (Oxford Medical Publications)

The first edition of this work appeared in 1908, and another edition has appeared every few years since. The book embodies the principles and methods of treatment of obstetrics as at present practiced at the Rotunda Hospital.

Part I deals with the reproductive organs Part II considers normal pregnancy, labor and puerperium

The first chapter in Part III is on the subject of toxemia, and the chapters that follow deal with other abnormalities of pregnancy, labor and puerperium. Part VI and VII are devoted to obstetric operations and care of the infant.

So much has been written in this country relative to the management of obstetrics and its complications as practiced in the Rotunda Hospital, that the contents of this book are fairly well known to the American physician. We are fairly in accord with the principles and practice which are set forth, and it is interesting to note the minor differences in obstetrical management which occur in this country

The book is an excellent text book, and very readable. It is well worth a place in the library of every obstetrician

W S S

THE CLIMACTERIC. (The Critical Age.) By GREGORIO MARANON Translated by K S STEVENS Edited by CAREY CULBERTSON, A B, M D Octavo of 425 pages, illustrated St Louis, The C V Mosby Company, 1929 Cloth, $6 50

The present edition is translated from the second Spanish one which appeared in 1925, and for this reason, the author has added some notes and bibliographic data, to bring the material up to date

The author has gathered together a large amount of material bearing upon, what he terms, the "Critical Age," and a large part of the book is devoted to sexual psychology The pluriglandular theory, and the general etiology of the climacteric symptoms are thoroughly discussed, together with the circulatory, psychic, metabolic, endocrine and digestive disturbances

One chapter is devoted to the critical age in the male, and considerable space is devoted to treatment.

The book is conceived from a broad point of view, and the subject is not treated from the narrow perspective, along which many gynecologists have been accustomed to regard the problems of feminine pathology It is written in a most interesting manner, and the text is interspersed with many editorial notes by Dr Culbertson.

There is a wealth of knowledge to be gained by a perusal of these pages, and the book is worthy of a place in the library of every physician.

W S S.

TUBERCULOSIS AND HOW TO COMBAT IT A Book for the Patient. By FRANCIS M. POTTENGER, A.M., M.D Second Edition. 12mo of 275 pages. St. Louis, The C V Mosby Company, 1928 Cloth, $2 00

This book is composed principally of a series of talks given by Dr Pottenger to his sanitarium patients in the hope that they may have a better understanding of the disease affecting them and cooperate more intelligently and effectively in their care. From these talks his patients may receive a clear idea of the nature of the disease, its source and mode of entrance into the body, its manifestations there and the significance of these symptoms especially at the earliest involvement.

In very short chapters are the symptoms and prognosis dealt with in a sufficiently comprehensive way to allay the doubts and fears of those sick.

The influence of the mind too, in intensifying or magnifying symptoms, in increasing the anxieties of absence from home, family or business and so retarding or hastening convalescence is well stressed in special chapters.

Treatment too, is explained and the purposes of and indications for rest, exercise, the sanitarium, the home, climate change and the reasons for the use of tuberculin are sufficiently and satisfactorily given. Throughout the book there is a cheerful, sensibly, optimistic tone. It is a deserved compliment that the hearers of these talks wished them placed in permanent form that they would be available to so many others suffering from this disease.

T A. McG

PRACTICAL CHIROPODY By E. G V RUNTING, F.I.S Ch. Third Edition. 12mo of 200 pages St. Louis, The C V Mosby Company, 1929 Cloth, $3 00

The author of this book, a chiropodist well known on both sides of the Atlantic has succeeded in presenting the essentials of practical chiropody in concise form.

The book is intensely practical, the chapters on corns, instruments and protective padding being particularly worthwhile

No book of comparable size presents a clearer picture of the scientific practice of the profession of chiropody and the author's work fully reflects the results of his forty years of experience.

BLUE RIBBON CHILD

The September issue of *Colorado Medicine* has the following editorial on the Blue Ribbon Child

"The Colorado Council of State-Wide Health Agencies, consisting of The Colorado Agricultural College, Extension Division, The Colorado Child Welfare Bureau, University of Colorado School of Medicine Hospital, Colorado Psychopathic Hospital, Colorado State Board of Health, Colorado Tuberculosis Association, Extension Division of Colorado University, Colorado Dental Association are sponsoring as a year-round May Day program a 'Blue Ribbon' Standard for children The adoption of the 'Blue Ribbon' standard is to place before child, parent and teacher the minimum standard of the physical ideal of childhood

"A 'Blue Ribbon' child is one who measures up to the minimum requirement for physical fitness on nine points 1, vision, 2, hearing, 3, teeth, 4, throat, 5, weight, 6, posture, 7, a reasonable degree of cooperation in control of communicable diseases (immunized against smallpox and diphtheria), 8, mental hygiene habits (adjusting at the child's intellectual and emotional level), 9, reasonable cooperation in the practice of personal health habits

"The child who is awarded a 'Blue Ribbon' certificate should be entitled to it because of his actual health knowledge, his use of such knowledge in eating, sleeping and playing, and in the improvement of his bodily condition in general An examination by a physician should determine whether the child is actually in physical health and free from defects as a result of his own and his parents' efforts

"A child who measures up to this standard will be awarded a 'Blue Ribbon' certificate for the year by the council The examination form must be signed by a physician or public health nurse, and the teacher The State Department of Health will award a banner to the county having the greatest number of 'Blue Ribbon' children by Dec 31, 1929, in proportion to population of the county as of the 1926 estimated report of the United States Census Bureau

"The motive of the 'Blue Ribbon' Standard is to encourage a periodic health examination for children

"The American Medical Association through its component state societies has been encouraging every physician to promote to the best of his ability the periodic health examination of each of his clients Pediatrists have found it possible to interest parents in the idea of a periodic check up of infants and young children with the aim of 'Keeping the Well Child Well' Life insurance companies have done much to educate adults to the truth that a periodic, annual check-up leads to health and longevity It is perhaps unfortunate that the reputable physician has had no adequate opportunity of advertising his genuine interest in the promoting of individual and community health The Blue Ribbon Standard offers such an opportunity

"When the physician examines a Blue Ribbon applicant, he has an opportunity to sell positive health to the parents as well as the child, and many of those contacts will become applicants for an annual health examination"

TRAVELING MEDICAL LIBRARY IN IOWA

The *Journal of Iowa State Medical Society*, in its September issue, has the following editorial description of the Medical Library of 10,000 volumes which is at the service of physicians

'As a great and growing institution which was created primarily for the use of Iowa physicians, the State Medical Library merits greater attention and more use on the part of State Society members The library has been fostered and aided by the Iowa State Medical Society from its inception and the existence of an active state society committee on the Medical Library further indicates how truly the library is a complement of organized medicine in this state

"Feeling that few physicians fully realize what the library offers them, the newly appointed librarian, Dr Jeannette Dean-Throckmorton, was asked to list the various services which are available to readers of the *Journal* They are

'1 Traveling Library Any volume in the medical section will be sent upon request, the borrower paying only parcel post charges

"2 Magazine Service Upon request from a physician a list of magazines will be sent from which he may make a selection for temporary use

"3 Bibliographies will be compiled

"4 Translations from foreign language journals will be furnished

PARTNERSHIPS IN GENERAL PRACTICE

The increasing number of New York physicians forming partnerships is evidence of the value of the plan Medical Partnerships is the title of an editorial in the September issue of the *Nebraska State Medical Journal* which reads

'This article is concerned with a restricted group of two or more physicians serving a community in general practice, and is not to be confounded with the group or clinic as generally understood It must be apparent to all that a partnership of two or more kindred spirits in the practice of medicine, at least in the smaller communities, must be an ideal way to practice medicine and infinitely better for the physicians concerned than to practice as rivals in the community The older practice of medicine has always been looked upon as largely a personal matter in which confidence in the physician was the most important In these days of scientific medicine, this personal equation, while still a matter to be reckoned with, is not any more considered all-important

"Service to the community is the all-important matter This can best be rendered by a system that will produce the best results with the least delay and inconvenience, and with a minimum of effort Let us assume a two-physician community in which the tributary trade territory is a ten-mile radius Practicing separately each physician may have a patient in the same certain neighborhood, ten miles out, requiring daily attention, requiring the efforts and time of both to attend, whereas, if the two physicians are united in their efforts, one can make the several

(*Continued from page 1228—adv xii*)

calls with little more time and effort than is required to attend to one patient In the meantime the other partner can minister to patients in another neighborhood or attend to calls in town or office Everybody concerned is benefited, a prompter service results, with less expenditure of effort, and more people can be served

"Daily consultations in the office in the absence of the patients are possible and profitable to physicians and patients alike In emergencies requiring an assistant or an anesthetist, calling the other partner is most convenient and agreeable.

"People knowing that two competent physicians work as a unit will be drawn to them in greater numbers when medical service is sought, thus increasing the income Two men working together can successfully conduct, if they will, an emergency hospital suited to the needs of the community They can the more fully equip themselves with *x*-ray and other laboratory apparatus and become more proficient in using it In such a partnership each one should be able to qualify in some special line of work in addition to the usual routine and in this way they increase their usefulness to the community and incidentally increase the income It is likely that two or more men practicing together have less annoyance from bad accounts than would either practicing singly

"The opportunities for rest, recreation, postgraduate study, attendance on medical society meetings, alternately, if need be, is easy as compared to the man who practices by himself

"The country doctor is not passing, but he must adapt himself to more up-to-date methods of procedure to attain the best results professionally, socially, financially and in the hearts of the community, and the outline above indicated offers a solution of the problem The country doctor must not much longer stand in the light of his own possible progress"

LIBRARY OF THE COLORADO STATE MEDICAL SOCIETY

A library service is conducted by the Colorado State Medical Society and is described in the September issue of *Colorado Medicine* as follows

"The Library of the Colorado State Medical Society, now comprising nearly two thousand volumes, is housed in the Metropolitan Building, in Denver, with the Library of the Medical Society of the City and County of Denver, which contains approximately twenty-three thousand volumes In this combination, the medical profession of the Rocky Mountain region is afforded library facilities superior to anything to be found between Chicago and the Pacific Coast. These two libraries are prepared to render to all mem-

GETTING FRUITS *and* VEGETABLES INTO *unwilling mouths*

When mothers bring you underweight, undernourished children who should eat plenty of fruits and vegetables but don't "like" them—why not prescribe Knox Gelatine vegetable salads and fruit desserts?

When vegetables or fruits are combined with Knox Sparkling Gelatine they have a new appearance—a different flavor. Children love the gelatine—they enjoy eating the fruits or vegetables. And the gelatine actually *aids* their digestion and increases the food value.

Knox Sparkling Gelatine is an excellent protein—it is a great aid to growing children. Be sure, when you prescribe gelatine, to specify Knox—the *real* gelatine. It contains many valuable amino acids promoting growth. Knox Gelatine is never flavored or sweetened—nor is any coloring matter added.

May we send you recipes for treating not only mal-nutrition, but diabetes, convalescence and other conditions? Our material on gelatine should be helpful to you—please check the booklets you wish and send us the coupon.

bers of the Colorado State Medical Society, the following important service

"1 Loans by title Upon request any book or journal will be loaned for one week

"2 Reference service·

"(a) Upon request, literature on any stated subject will be found and forwarded

"(b) As received, current journals will be searched for articles on a stated subject and appropriate issues forwarded to those members requesting this service.

"3 Journal service Two hundred and twenty-eight medical journals are received regularly Any member of the State Medical Society may select a journal or a number of journals which he would like to receive regularly and these journals will be loaned for one week.

"All loans of books and journals are subject to the usual library rules, and the sole costs are the transportation charges, both ways

"During the past year, fifty-six calls for service were received from members residing outside of Denver, and one hundred and seventy-five items were shipped In addition, service was rendered at the library to one hundred and five members making personal calls

"Many members of the State Society must know of this invaluable service to be had for the asking, it is apparent that, at this time, comparatively few are availing themselves of it. It is confidently believed that with a little publicity generally appreciation of the library's keen desire to be helpful will be rapidly succeeded by steadily increasing demands for service."

ROUND-UP OF SCHOOL CHILDREN OF IOWA

This *Journal* of March 1, page 302, carried an abstract of an article on the health round-up of school children conducted by the Parent-Teacher Associations in 1928, when 126 committees carried on the work Thus more than 200 communities took up the work which is described as follows on the "State Health Commissioners Page" of the August *Journal of the Iowa State Medical Society*

"The movement known as the Summer Round-up and sponsored by Parent-Teacher Associations throughout the country is being conducted this summer by more than 200 groups in Iowa The object of the movement is to have every child who is to enter school for the first time next fall, examined for physical defects or disease conditions and to have such corrected so far as possible Various methods for conducting preliminary examinations have been employed

"The following letter sent by the secretary (Dr L K. Meredith) to all members of the

NASON'S

. . the friendly flavored Cod Liver Oil

HERE'S a cod liver oil that creates no "hard feelings"—for it isn't hard to take! After all the thorough work of refining is done, a fractional percentage of a special flavor is added of highest vitamin potency

Nason's palatable cod liver oil complies with the U S P Standards for cod liver oil In addition, it is required to have a content of fat soluble vitamin A, determined by the U S P method, of not less than 800 units per gram and an antirachitic potency such that 0 01 Gm per day will produce definite healing (as determined by x-ray photographs), in the leg bones of rachitic rats in eight days when added to a diet lacking in vitamin D, the rats being also deprived of ultraviolet light

Ask us to send you a sample of NASON'S!

Marion County, six speakers to six meetings, St Francois County, ten speakers to four meetings, and scattered throughout the state are special requests coming from societies for one or two speakers during the year The Committee feels that the best influence from the Postgraduate Course can be obtained by providing two or more speakers for counties where an audience of from 25 to 50 people will be assured For the smaller counties a speaker could be provided at least four times a year Many of these smaller counties meet only quarterly, so the Committee is ready to aid them at every meeting

"Forty speakers have responded to calls this year for 59 meetings We find the members of the Association respond to our request for their time and energy to carry out the purposes of the Postgraduate Committee with great willingness and at the sacrifice of personal convenience Societies usually ask for the particular men they want and the particular subject they want so that your Committee cannot be accused of favoritism or praised for the well rounded out selection of subjects that have been presented

"The expenses of the Committee were $942 82"

MEDICAL DEFENSE IN MISSOURI

The report of the Committee on Defense of the Missouri Medical Association printed in the July issue of its *Journal* says

Cases pending May 1, 1928	17
Threats pending May 1, 1928	5
New cases during the year	8
New threats during the year	5
Cases settled during the year	12
Threats which did not develop into suits	7
Threats pending May 1, 1929	3
Cases pending May 1, 1929	13
Financial assistance rendered during 1927-1928	$300 00

"We feel that this is a rather favorable report and that conditions are somewhat better than last year We have only thirteen cases and three threats pending, as against seventeen cases and five threats of last year

"Out of the ten threats recorded, seven have been disposed of in one way or another Of the twelve cases settled during the year, seven were dropped or withdrawn, three resulted in verdicts against the physician, one verdict in favor of the defendant and one was a hung jury

"We feel that what improvement has been made is due largely to the unselfish cooperation of the physicans throughout the state. Your committee feels that this growing cooperation will do much to discourage the filing of unwarranted malpractice suits, which most of them are"

PUBLICITY BY IOWA MEDICAL SOCIETY

The report of the Secretary of the Iowa State Medical Society published in the July issue of the Journal, touches upon publicity work, especially that of its Journal, and the Speakers' Bureau It says

"We have tried definitely to make the Journal a source of reference and news, as well as of scientific information Since your Journal accepts only council approved products, its advertising pages should serve as a continuous scientific exhibit For your easier reference the advertisements have been classified by products and are monthly indexed.

"Every county society news item that comes to our attention is printed We have a newspaper clipping service, but it is far from getting all the news. Several of the secretaries send well written, interesting reports of their meetings and we hope that more will do so in the future. We are endeavoring to make the Journal a clearing house of county society activities so that progress which some counties are making in public health relations and in various phases of medical economics may be passed on to the sister societies

"Of a personal nature are the news notes that appear monthly and the want ad column which is growing and continually producing more replies so that it is on the way to become a professional placing bureau.

"The larger aspects of the new policy, the book reviews, the editorials and scientific papers are best left to description by the editor, since it is for the dissemination of scientific information that the Journal primarily exists

"Evidence is accumulating to show that the Journal is being more and more read That the Journal may become a vital thing in the life of every member of this Society is the hope of your editor and his assistant My specific duties are manager of advertising, preparation of society, personal, and miscellaneous news items, proof reading, and make-up

"Important as the scientific pages of the Journal and the scientific meetings of the state session are, it still remains that the vast majority of all scientific matters and discussions are represented by the county society programs A few societies meet but one or twice a year, but the bulk of them in Iowa convene between four and ten times, yearly, and I would estimate that there are nearly five hundred county and district society meetings held annually in the state If the average attendance is between fifteen and twenty, we would have a total aggregation of eight or ten thousand auditors, beside which this state session is a very small affair Consequently the supplying of county society programs is an undertaking of first importance, and the council is promoting a speakers

COUNTY GROUPS IN THE STATE MEETING

An editorial in the August issue of the *Pennsylvania Medical Journal* suggests that each county medical society organize a group to attend the State meeting. The editorial is as follows

'The suggestion has been made that each county medical society organize a group to attend the Erie Session (September 30 to October 3, 1929) in a body If this is to be done, now is the time to start the plans There are still a few vacant rooms at the Hotel Lawrence, and if reservations are to be secured there, prompt action must be taken.

'It is natural for those who have not been to State conventions to feel a certain hesitancy about going alone It is so much more pleasant to have company, and still more delightful to have the support of a group of home folk. This provides a background for the enjoyment of contacts with physicians from all over the State, and is insurance against the homesick feeling that may afflict the lone visitor when he first arrives This feeling soon disappears, however, after he gets into the spirit of the occasion, for there are so many delightful contacts to be made, so many social events to fill the time to overflowing that there is little time left to feel homesick. These State Society conventions are just about the friendliest places imaginable, and our aim is to make them still more friendly To this end group attendance is suggested as a means of breaking the ice and starting the habit of going to the State Society meeting every year Then you look forward to seeing the old friends and making new ones, and each year it becomes more of a pleasure to pack the grip and away for a week of combined education and social intercourse with your own kind

"Several years ago, one of the county societies chartered a bus for a day and went in a body to a State Society convention in a near-by city It was voted a great success, and more county societies are urged to try it '

bureau which will supply scientific papers or programs for the component societies Forty-one such programs were furnished on the subject of cancer, principally during the month of February, and about twenty-five other programs have been contributed to, generally in the field of medical economics A list of qualified speakers is being prepared and in the future this development should be of great value

"This same speakers bureau is preparing to supply qualified physician speakers for lay gatherings In this day when quackery is being spread through women's clubs and public gatherings by clever orators, such a lay speakers bureau is a vital necessity Certainly no greater service could be rendered to the individual physician of this state than to educate his public as to the true merits and possibilities of scientific medicine Calls are already coming in and the public health relations committee of the council has established contact with a number of state organizations and clubs interested in public health through which the speakers bureau can arrange for talks on health and hygiene, and merits of scientific medicine to be made before lay audiences, women's clubs, P-T A , etc Your managing director made an announcement of this sort at the last annual meeting of the Iowa Tuberculosis Association and is to make a similar statement at the Iowa district meeting of the Lions Club next week It is hoped that before the end of this year a large number of health educational addresses will have been made by members of this Society

ADVERTISING IN THE TEXAS STATE JOURNAL

The July issue of the *Texas State Journal of Medicine* makes the following appeal to the Woman's Auxiliary to support the advertisers

"Now that we are publishing our own, and are conducting a department in the *Journal* for the Auxiliary, it would seem quite appropriate to call attention to the fact that our advertisers would like to talk to them, also It would seem that this is one line along which the Auxiliary could go a great distance in helping us There are numerous messages of interest to the women in each issue, and we believe our advertisers will be more than glad to hear from any of them, at any time

"As a matter of fact, the women are interested in many of the advertisements that their husbands are interested in, and for the same reason, but there are ads of special appeal to them, such as the Gale Abdominal Belt, to mention them as we come across them in the previous number, Knox Gelatine, the Sugar Institute, counter offensive to the 'Reach for a Lucky Instead of a Sweet' attack, Nonspi, Camp Corsets and Supporters, Bolen Supporters and Binders"

THE HEART EXHIBIT AT THE 1928 ANNUAL MEETING

FOREWORD

The annual meeting of the Medical Society of the State of New York, held in the State Armory at Albany, May 21-24, 1928, was notable for its heart exhibit, which was arranged and conducted by a special committee consisting of Dr Robert H Halsey, chairman, and Drs Joseph H Bainton, Louis F Bishop, Hermon C Gordinier, William H Lohman, Bernard S Oppenheimer, Harold E B Pardee, Edward C Reifenstein, and Nelson G Russell

The exhibit was conducted in three parts

1 An exhibition of charts, statistical tables and pathological specimens, which was open to inspection during the entire time of the annual meeting

2 Lantern slide demostrations, principally of microphotographic studies

3 An open meeting and addresses on May 24

The charts and other wall exhibits are described in the paper by Dr La Chapelle A large number of them have been published in the volume which constitutes the report of the Special Committee on Heart Diseases, of which Dr Robert H Halsey was Chairman

The Pathological exhibits are described in a paper by Dr Bainton

The addresses have been collected and edited, and are now assembled and published in a group, together with the discussions

THE CARDIAC EXHIBIT AT THE STATE MEETING*

By J H. BAINTON, M.D, NEW YORK, N Y

THE Cardiac Exhibit at the annual meeting of the State Medical Society was planned at the request of the Committee on Scientific Work

It was particularly appropriate that this demonstration was presented at a meeting in which the subject of heart disease played such a prominent part At the business meeting of the House of Delegates the comprehensive report of the "Committee to Make a Study of Heart Disease in the State" was unanimously accepted, and a special combined meeting of the sections on Public Health and Medicine was devoted exclusively to Heart Disease.

This cardiac demonstration was the most pretentious both in size and scope ever presented and would have been impossible without the generous assistance given by many individuals and organizations The demonstration was divided into three parts 1—A pathological exhibit, 2—A wall display, 3—Short lectures illustrated by lantern slides and motion pictures

The pathological exhibit is described in a separate article by Dr C E de La Chapelle who prepared and arranged this part of the demonstration

The wall display covering a distance of 110 feet was planned with the idea of presenting not only statistical data but also many outstanding factors of clinical significance The titles of the subjects were as follows—Mortality, morbidity, etiology, diagnosis, organized care, therapy, the effect of disease on the contour and structure of the heart, pathological physiology

Mortality—10 charts presenting statistical data of deaths from heart disease throughout the United States Registration Area These charts, the work of Miss Jessamine S Whitney, were loaned by the American Heart Association

Two charts on death rates in New York State and a chart on death rates in 16 large American cities, prepared by Mr G J Drolet were loaned by the Heart Committee of the New York Tuberculosis and Health Association One chart which was especially prepared for the exhibit brought out the fact that there are no statistical data on the Mortality

where it was impossible to show all of them in one setting of a specimen, for example, where three valves were involved

Following the general trend of the cardiac program, particular reference was made to etiology The specimens were therefore classified on an etiological basis rather than on an anatomical or morphological basis as usually employed

The etiological classification used was the one approved by the Committee on Research of the American Heart Association (1) Although there are ten groups in the official listing, only seven of these were used in the exhibit, the "Unknown," "Toxic," and "Neurosis" groups being excluded, there having been no specimens to exemplify these groups An additional group, i e "Tumors of the Heart," was exhibited, making a total of eight groups presented for demonstration

The groups demonstrated were as follows —

1 Rheumatic Heart Disease
2 Syphilitic Heart Disease
3 Bacterial Infection of the Heart
4 Thyroid Heart Disease
5 General Systemic Disease
6 Traumatic Heart Lesions
7 Tumors of the Heart
8 Congenital Developmental Defects

Group 1 *Rheumatic Heart Disease*—Included in this group were those specimens of rheumatic infection of the heart illustrating the various lesions of activity or inactivity, or both, as commonly met with in this type of heart disease

The first specimen demonstrated was the heart of an individual who died during her first attack of rheumatic fever There was no pericardial involvement but the valvular lesions were very prominent. These consisted of minute, cauliflower vegetations distributed along the line of closure of œdematous mitral and aortic valves Microphotographs showed the true valvulitis beneath the endocardial lesions and also the myocardial reaction which could not be seen grossly, namely, the numerous Aschoff bodies scattered throughout the myocardium

Another specimen presented the typical acute pericardial lesion of acute rheumatic fever This same specimen demonstrated active infection (valvulitis) implanted on an inactive lesion of the mitral valve

Mural involvement in rheumatic heart disease was demonstrated by a specimen with involvement of several centimeters of the wall of the left auricle by minute, warty excrescences raised above the surface of the mural endocardium Involvement by an active process of the mitral, aortic and tricuspid valves was also exhibited in this specimen

A heart with far advanced inactive valvular disease but with an active infection (endocarditis) implanted on three valves was presented to show the association of an active with an inactive rheumatic process in a heart which had had many attacks of rheumatic infection, and to show that tricuspid involvement is not rare

A few specimens of inactive rheumatic valvular disease, exhibiting the various types of valvular deformity, e g, mitral stenosis, aortic stenosis, aortic insufficiency, tricuspid stenosis, and the various combinations of these lesions, were demonstrated

Microphotographs in this group included views of acute rheumatic valvulitis during the first attack, another of activity on an inactive sclerotic valve, a third with the typical Aschoff bodies in the myocardium, and another showing the acute pericardial reaction

Group 2 *Syphilitic Heart Disease*—This group included mainly specimens of syphilis of the aorta and its sequelae, e g, dilatation, aneurysms, aortic valve and coronary artery involvement Two specimens presenting myocardial involvement were also exhibited

The first specimen of syphilitic myocardial disease presented a very rare lesion, namely a ruptured gumma of the ventricle The second exhibited irregular gummatous nodules in the left ventricle with infiltration of the myocardium Microphotographs taken of sections from both specimens were also shown

The first specimen of syphilis of the aorta merely showed a simple aortitis without dilatation The second presented involvement of the aortic arch with almost total occlusions The third specimen showed dilatation of the ascending aorta without valve involvement, another with the same condition but with a dilatation of the aortic ring producing an insufficiency without the cusps themselves being involved This last type of specimen is not a frequent finding at autopsy

Aneurysms of the aorta varying in size, type, and location were demonstrated Specimens exhibiting different points of rupture were also shown, e g, rupture into a bronchus, a lung, the esophagus, and pericardial cavity Erosion of vertebrae by an aneurysm was also demonstrated

Coronary artery involvement was demonstrated by a specimen presenting syphilis of the aortic arch with almost total occlusions of the mouths of both coronary vessels, and subsequent myocardial changes, e g, fibrous tissue replacement, due to a disturbance in nutrition of the muscle fibers There were no syphilitic changes in the vessels themselves in this specimen Syphilitic involvement of the coronary arteries was demonstrated by a

of heart disease from the standpoint of etiology

Morbidity — Comparatively little work has been done on this subject and statistical data are very meagre Two tables on Chronic Valvular Disease from A E Cohn's work were reproduced in enlarged form

Etiology—Five charts were employed to present this subject, Incidence of Organic Heart Disease arranged by age groups and etiological types, by Wyckoff & Lingg, Syphilis Age, Incidence, and Duration of Syphilis before onset of symptoms by Stokes, three tables from Homer F Swift, one on rheumatism, one rheumatic heart disease and one on the number of hospital days required in individual cases of rheumatic fever

Diagnosis—That the diagnosis of heart disease is complete only when four points have been determined, etiology, anatomical lesion, physiological disturbance and functional capacity, was the subject of one chart. A second chart explained the criteria for classification according to functional capacity of the heart.

Organized Care — That this question has not received widespread consideration is quite evident from the fact that only two chartss were available for exhibit purposes, one on the Organization of a Heart Clinic, the other on the Organization of Vocational Guidance Service

Therapy — A graphic representation of the effect of therapeutic measures is necessarily limited in scope Charts were prepared for this exhibit from observations made on Dr Wyckoff's Service in the Third Medical Division of Bellevue Hospital These charts illustrated the effects of digitalis and oubain on patients with auricular fibrillation and auricular flutter

Structural Lesions of Heart Disease

Teleoroentgenograms — Twenty - four teleoroentgenograms loaned by Dr I A Landsman, director of the *x*-ray laboratories of Bellevue Hospital, showed the changes in size and contour resulting from the common valvular lesions Aneurisms at different sites of the aorta were also shown

Smithsonian Charts — Copies of the charts from the cardiac exhibit of the Smithsonian Institution demonstrated a comparison of the interior and exterior of normal and diseased hearts.

Pastels — Four original drawings in colors by Dr C E de La Chapelle depicted the natural appearance, postmortem, of various cardiac lesions (1) Acute rheumatic carditis showing pericarditis and endocarditis, (2) Streptococcus viridans endocarditis, (3) Streptococcus zymogenes endocarditis, (4) Coronary thrombosis

Pathological Physiology

Electrocardiograms — A comprehensive set of electrocardiograms was arranged and mounted especially for this exhibit by Dr Alfred E Cohn They demonstrated nearly every known form of irregularity and conduction defect In some tracings the three leads were produced synchronously by three galvanometers

A Study of Heart Disease in the State of New York

Twenty-one charts from the Committee's Report were selected for presentation in the exhibit They were especially eloquent because they applied to problems within the State Members who were unable to attend the meeting still have an opportunity of studying these charts within the pages of the Report

The third part of program reserved for the final day was devoted to illustrated lectures on heart disease

In the morning there were 4 talks Dr Emanuel Libman exhibited a film showing various lesions of sub acute bacterial endocarditis There were three groups of microphotographic studies, Dr William C von Glahn presenting "The cardiovascular lesions in rheumatism," Dr Louis Gross "The blood vessels in the heart valves and their relation to endocarditis," Dr Joseph T Wearn "The relation of coronary circulation to heart disease."

The program was concluded with cinematographic studies of "heart block" by Dr Samuel W Lambert, of "heart valves in action" by Dr Robert H Halsey, and of "cells cultivated in vitro" by Drs Albert H Ebeling and Alexis Carrel

---

THE PATHOLOGICAL SECTION OF THE CARDIAC EXHIBIT*

By CLARENCE E DE LA CHAPELLE, M D, NEW YORK, N Y

THIS section of the Cardiac Exhibit included a demonstration of 120 gross specimens of the various types of disease of the heart and aorta Accompanying most of the specimens was an abstract of the clinical data of the case and a description of the postmortem findings Microphotographs of the main lesions represented were on view with the respective groups Photographs of gross lesions were employed in those instances

* Exhibited at the Annual Meeting of the Medical Society of the State of New York, at Albany, N Y, May 22, 23 24, 1928

men of Monckeberg's sclerosis also was demonstrated

Among the aortic lesions were demonstrated specimens with sclerotic and calcific changes in the aortic valve A specimen of sclerosis of the mitral valve with stenosis from an individual 80 years old was exhibited No evidence of rheumatic infection was found in this specimen Another specimen of calcification of the annular ring of the mitral valve, producing an insufficiency of the valve, was presented

In the coronary artery section were demonstrated the different lesions of these vessels, such as simple sclerosis, sclerosis with occlusion by a plaque, occlusion by a recent thrombus, and occlusion by an old calcified thrombus This same group of cases showed the various sequelae to coronary artery disturbances A specimen of a recent infarction of the ventricle, showing involvement of the endocardium (thrombusformation) and the pericardium (fibrinous pericarditis), was exhibited The occluded coronary vessel (ramus descendens of the left coronary) was readily seen Another specimen showed the end result of healing of an infarct, namely sclerosis and fibrosis of the endocardium and myocardium with a localized area of adherent pericardium over the original insult. In this specimen the thrombosed vessel had become hyalinized at the point of occlusion In contrast to this latter specimen there was exhibited a heart, from a man 70 years old, with a calcified plaque totally occluding a main coronary vessel yet the myocardium being absolutely intact This type of case, though rare, nevertheless is very important since it emphasizes the fact that in the later decades the vascular supply of the heart is prepared to compensate for an occlusion of even a main coronary vessel by means of its abundant anastomoses

A calcified left ventricle, an aneurysm of the left ventricle, and a ruptured heart, all three the result of coronary occlusion, were a few of the specimens exhibited in this same group An x-ray photograph of the calcified heart accompanied the specimen

A specimen from an individual dying of uraemia at 33 years with a history of scarlet fever in youth, with marked hypertrophy of only the left ventricle was exhibited together with a pair of markedly contracted kidneys, as an example of the type of heart found in chronic nephritis

A "hypertensive" heart was demonstrated by a specimen with hypertrophy and dilation of the left ventricle, left auricle and right ventricle, coronary sclerosis associated with marked arteriosclerotic changes in the kidneys

A heart from an individual who had died of pernicious anemia was exhibited as a specimen of fatty degeneration The myocardium was pale yellow in color A microphotograph accompanied the gross specimen.

To illustrate gross fatty infiltration, a heart from an obese individual dying of alcoholic poisoning, showing a thick layer of fat covering the epicardial surface and infiltrating the muscular wall of the auricles and ventricles which in turn were very thin, was displayed A microphotograph of a section from this specimen showing fat droplets between the muscle fibers adjacent to the epicardium was on view

A small heart with tortuous coronary arteries, a markedly wrinkled pericardium, and whose myocardium was dark brown in color, was presented to typify brown atrophy This specimen was taken from a man who had diabetes mellitus

A specimen with a markedly hypoplastic aorta and with a ruptured aneurysm of a coronary artery was presented to show the changes in the vascular system in status lymphaticus

Group 6 *Traumatic Heart Lesions*—This group included a few specimens of trauma to the heart and aorta The first specimen presented a large, irregular tear in the left ventricle, not associated with any abnormal myocardial or endocardial changes This heart, an example of traumatic rupture, was from an individual whose chest wall had been crushed Another specimen presented a ruptured aneurysm of the descending aorta without evidence of disease of the vessel either grossly or microscopically A history of trauma to the chest six months before death had been elicited Although the rupture was spontaneous, the cause of the aneurysm was undoubtedly trauma The third specimen in this group was one presenting a bullet wound perforating, in the line of involvement, the right ventricle, mitral valve, left auricle, and the left ventricle

Group 7 *Tumors of the Heart*—This was the additional group spoken of previously, and included new growths, both primary and secondary, and cysts A few of the specimens presented were as follows, primary sarcoma, metastatic sarcoma, melanoma, hypernephroma, and adamantinoma of the heart An echinococcus cyst of the left ventricle was also presented Micro-photographs of sections taken from all of these tumors were on view

Group 8 *Congenital Developmental Defects*—This group included about 25 specimens of anomalies of the heart, divided and classified according to the classification of Maude Abbott. (2)

These were listed as follows —

1 Displacements
  Ectopia cordis
  Dextrocardia

specimen of aneurysm of a coronary artery associated with syphilitic aortitis

Group 3 *Bacterial Infection of the Heart*—In this group were collected those specimens with disease of the structures of the heart resulting from infection by the pneumococcus, streptococcus (both the hemolytic and the viridans types) the staphylococcus, gonococcus, and the tubercle bacillus

The specimens of streptococcus endocarditis were separated into an individual subdivision and exhibited as such, together with a specimen of micrococcus zymogenes and one of Brucella melitensis endocarditis Both of these latter specimens were from cases who were typical examples clinically of subacute bacterial endocarditis and hence were included in the streptococcus group

A The pneumococcus specimens showed the various lesions found in this type of bacterial infection of the heart The first presented an early lesion on an aortic valve from a case of lobar pneumonia The second showed the same picture except that the aortic valve was congenitally bicuspid The third was a specimen with an ulcerative lesion of the aortic valve with the direct involvement of the myocardium and with perforation of an aortic leaflet Another specimen presented vegetative lesions on all the valves but the aortic, which is the valve generally involved

The pericardial reaction in pneumococcus infection was demonstrated by a specimen of a dilated pericardial sac filled with a large amount of pus but with no involvement of the valves of the heart

B One specimen of gonococcus infection of the heart was presented This exhibited a large friable thrombotic vegetation on the aortic valve with ulceration of one cusp and with involvement of the intima of the aorta

C In the staphylococcus group were demonstrated several specimens of staphylococcus aureus infection of the heart One showed only a serofibrinous pericarditis (taken from a case of osteomyelitis in a child of ten) The others presented various lesions of the valves, with and without destruction of the valves and the myocardium Two presented prominent embolic features, namely, infarcts of the spleen and kidneys, together with multiple abscess formation of the kidneys in one of the specimens

D In the streptococcus division only one case of hemolytic streptococcus infection was exhibited showing small vegetations on the mitral and aortic valves simulating rheumatic endocarditis

Several streptococcus viridans specimens were displayed to present the various lesions of the heart and associated organs, i e, spleen and kidneys, found in this type of infection The first specimen was one of primary tricuspid endocarditis without previous valve involvement Another presented a typical lesion of viridans endocarditis implanted on an old rheumatic mitral valve, showing the frequently found mural lesion of the auricle and ventricle, and involvement of the chordae tendineae, there was also an embolus in one of the coronary arteries A third specimen presented a typical lesion on an inactive rheumatic aortic valve associated with a cerebral hemorrhage, infarcts of the spleen and a typical "flea-bitten" kidney The brain, spleen and kidneys were demonstrated in this instance, as were also microphotographs of the kidney lesions

Two congenital hearts with viridans infection were exhibited with this group to emphasize the tendency of streptococcus viridans to attack this type of heart The one was an example of coarctation of the aorta with a viridans lesion of the mitral and tricuspid valves The other was a case of patent interventricular septum with the viridans lesion implanted directly on the congenital defect.

The specimen of micrococcus zymogenes presented a lesion on the aortic valve similar to that found in the viridans specimens

The specimens of tuberculosis of the heart included one with myocardial involvement, and several with the various pericardial reactions, i e, adherent pericardium with caseous necrosis between the layers, adherent pericardium without a gross tuberculous lesion, and another with a markedly dilated pericardial sac filled with serous fluid from an individual dying of advanced pulmonary pthisis Microphotographs accompanied these specimens

Group 4 *Thyroid Heart Disease*—Two specimens of marked enlargement of the heart associated with changes in the thyroid were demonstrated in this group of heart disease. Microphotographs of sections taken from the thyroids were also exhibited.

Group 5 *General Systemic Diseases*—In this group were exhibited the specimens of arteriosclerosis of the aorta, coronary arteries, and the hearts with lesions which were the sequelae of coronary artery occlusion, e g, infarction, fibrosis, calcification, aneurysmal dilatation, and rupture Here also were found the hearts associated with chronic nephritis, hypertension, pernicious anemia, and diabetes mellitus

Arteriosclerotis lesions of the various portions of the aorta, i e, ascending, arch, thoracic, and abdominal, were exhibited Different degrees of sclerosis were shown in these specimens, from simple sclerosis to calcification with ulceration and thrombosis A speci-

what may be called a technical language, or a real vernacular In view of this requirement a preliminary criterion of nomenclature must be formulated and this has been done

To describe similar conditions of patient and heart, the same terms and expressions must be exactly used Therefore criteria of clinical and pathologic diagnostic application, based upon the nomenclature must be available for all physicians to use when confronted with the elements Such criteria must state the distinctive factors when known and the most common distinguishing features are the etiologic. To devise appropriate measures of relief or to correct defects it is essential to recall the evidence by which damage to the heart may be recognized This depends upon changes in the anatomic structure or in the physiologic action and these changes depend upon some etiologic factor A complete description of the condition of the heart, therefore, requires a statement of the structural condition, the physiological performance and the etiologic factors responsible for the production of the condition of each.

But the individual with a damaged heart is to some degree incapacitated for carrying on his physical activity or work. To properly supervise those with a cardiac impairment or intelligently advise them concerning the character and amount of actual work or play to be permitted it is essential to know something of their work or exercise tolerance. The worker seeking employment must be informed as to the amount and kind of work he may do without risks of further injury to himself

The employer of labor from tradition, and, perhaps too, from unhappy experience, dreads to employ a handicapped heart The fear, due to ignorance of the condition, is not altogether justified and knowledge obtained from an examination may properly classify the applicant or employee and permit the candidate to fill satisfactorily the properly selected job As yet industry has not recorded its experience of this kind in such a manner as to make it available to all or demonstrate what may be done to safely employ cardiac cripples

The legislatures have, in many states, passed liability laws which unjustly penalize both the employer and the employed

The intelligent supervision of a person with a damaged heart requires, therefore, that the physician be informed of the etiology, anatomic and physiologic defect and the functional capacity of the individual to carry-on The four elements are necessary for a complete understanding of the cardiac problem.

The hospitals of the state are havens of hope and expectation for those with disease The hospitals and medical schools must ever be examples of the most exact diagnosis and tender care of patients At the same time they must observe new facts and tabulate the same in such a way as to continually stimulate emulation The best equipped minds of the profession must prescribe for relief and cure and, as in laboratories, investigate and teach the newer facts of disease by observation on the living From the dead at the necropsy must be gleaned each single fact which elucidates the individual problem and requires the expert skill in the gathering to become increments in the advance of knowledge Yet it is only now the systematic tabulation of observations is making possible the answers to questions bearing upon etiology and natural history There is now available a complete practical system of describing cardiac conditions in terms etiologic, anatomic and physiologic and a systematic method of filing them

The outline followed in the past has taken as a guide the International List of Causes of Death but this method is in some respects antiquated and inadequate because of the vague terms, the group headings are not mutually exclusive and etiology is not required Suggestions for revision have been made which overcome in part this omission and are more in keeping with our present knowledge

To plan an effective attack upon the broad problem of heart disease, as a social and public health problem, all of the knowledge bearing upon individual cases must be known and considered to guide the evolution of the project

The plan suggested, of placing the etiology upon the office and hospital records, will make it possible to place the same on the death certificate In this way it will be brought to the statistical bureau of the Departments of Health where it can be tabulated and help to make the problem of heart disease more accurately and easily comprehended As yet these statistics are non-existent but, for a true conception of the problem, they are required

A society composed of medically trained minds connotes not only special training but special interest and equipment for special service to the individual and to the community

Special knowledge means leadership with live leaders, leaders who are not monumental mortuaries, leaders eager to publish and diffuse the facts they have and quick to observe and apply new facts Mind may not have been always the directing force in evolution, yet much may be accomplished by formulating a method of approximating our ideas and ideals This means creating those conditions in our profession which the consensus of the well trained physician demand and practice

This State Society has stepped into a leading position in undertaking to learn about heart disease as it affects the people of this State. It is, therefore, right, proper and opportune that it

2 Anomalies of the heart as a whole
Rhabdomyoma of mitral valve
3 Anomalous septa
Of the left auricle
Of the right auricle
4 Defects of interauricular septum
Patent foramen ovale
Deficient auricular septum
5 Defects of the interventricular septum
Defects at the base, single and multiple
Aneurysm of undefended space with bacterial lesion
6 Pulmonary stenosis
Stenosis alone
Stenosis with associated lesions
7 Dilatation of the pulmonary artery
Dilatation of the conus
8 Congenital aortic stenosis or atresia
Stenosis with atresia of left ventricle
Subaortic stenosis
9 Anomalies of the semilunar cusps
Bicuspid aortic
With and without bacterial lesions
Bicuspid pulmonary
Supernumerary pulmonary
10 Anomalies of the ductus arteriosus
Persistent
Partially patent with closure of aorta
11 Coarctation of the aorta
Infantile type
Adult type with associated anomalies
Adult type with associated anomalies and extensive collateral circulation

Included in the Pathological Section of the Cardiac Exhibit was an exhibit of injected human hearts showing the blood supply to heart muscle and valves These were on display through the courtesy of Doctor Louis Gross, Director of the Laboratories of the Mount Sinai Hospital, New York City, and served as an adjunct to Dr Gross's illustrated lecture on "Blood Vessels in the Heart Valves and Their Relation to Endocarditis," given before the Society on May 24th

The main purpose of the Pathological Section of the Cardiac Exhibit was to demonstrate the various diseases of the heart and aorta by means of gross specimens Secondly, to show the possibility of classifying and exhibiting pathological heart specimens on an etiological basis, since, as mentioned previously, the general trend of the Exhibit was to put particular stress on the etiology of heart disease

The Pathological Section also emphasized the importance of hospital necropsy reports, offering as they undoubtedly do, a source of information not alone as to pathology but also as to etiology (3) From the Pathological Laboratories, Bellevue Hospital, Dr Douglas Symmers, Director, and the Third (N Y University) Medical Division, Bellevue Hospital, Dr John Wyckoff, Director

HEART DISEASE—THE BROAD VIEW *

By ROBERT H HALSEY, M D, NEW YORK, N Y

THE term "heart disease" is not descriptive of a single clinical entity, such as is connoted by typhoid, diphtheria, or diabetes, for, it does not describe a "definite process having a characteristic sequence of symptoms"

The term includes many and varied processes, some of which may be active or inactive, of short or long duration and may have produced structural deformities or physiological defects Some of the deformities may have been due to developmental defects, or disease occurring during intrauterine life, while others may have been acquired after birth The term is applied to results of bacterial growth located within or without the heart, to the results of toxins, to general systemic diseases, or to disordered function of the endocrine glands

The term is equally misapplied without distinction to the anatomical deformities resulting from disease and to deformities common to several diseases It is improperly applied to symptoms which are the expression of disease, as pain (angina) and pressure (hypertension), and terms indicating active, productive processes, in complete abeyance of intellectual honesty, are sometimes knowingly misappropriated when degenerative changes are known to be taking place.

Terms descriptive of imperfections of size, shape and consistency and function do not give an inkling of the causative factor but only describe the damage already done

Where there is now a babble of medical terms there might be a common language In place of a confusion of expressions there might be systematic, orderly, concise statements which would be more correctly understood This would please in the expression, delight in the ease of apprehension and constitute clarity, convenience, efficiency and progress

To transmit thought or conceptions, from one to another it is essential to employ accepted characters and groups of characters which compose

*Read at the Annual Meeting of the Medical Society of the State of New York, at Albany, N Y, May 23, 1928

better appreciation of the part played by heart muscle in all cardiac disorders along with a healthy skepticism has brought about a complete change in our conception of mitral insufficiency To be precise the actual change in our ideas concerns the significance of systolic murmurs heard in the region of the apex of the heart The assumption formerly was that such a murmur indicates a puckering of one of the valve cusps, a valvular disease There has been a critical attitude toward murmurs which has resulted in a quite variable interpretation of the significance of murmurs in general and especially of these mitral systolic murmurs While anyone today will agree that this is possibly the *most common murmur* heard over the heart, no one believes that simple mitral insufficiency is a common lesion, in fact it is quite uncommon If the patient has had some infection which is prone to injure the heart valves there is the possibility that a systolic murmur may mean a valve lesion In the absence of such an etiological factor one is justified, if the patient is young, in being skeptical about the matter On the other hand, if the patient is in middle life, or older, and especially if there is a history of vascular hypertension, one would not think of a valve lesion at all but of a condition far more serious, namely the beginning of cardiac insufficiency This particular murmur, then, has been wholly stripped of any specific meaning which it once had and today it is interpreted in the light of possible etiological causes of heart disease Developing after an infection it might mean one thing—a slight valve lesion Developing late in life it means quite another type of heart disease In order to understand a murmur it becomes necessary to think of it as a result of an infection, or a result of some constitutional disorder, such as arterio-sclerosis, or severe anemia, or as a congenital anomaly

Diastolic murmurs are more reliable evidence in diagnosis than systolic murmurs and a diastolic murmur heard at the sternal margin is often regarded as a conclusive sign of abnormal aortic valves Yet there are cases reported where such a murmur had been present for years and no lesion of any sort referable to the heart found at autopsy, hence the term "accidental" murmur How does one differentiate clinically? On the basis of etiology primarily, if the patient is young and has had rheumatic infections, or if he is in middle life and has had syphilis, or if he is old and has arterio-sclerosis, the diagnosis of aortic valve disease is sound and confirmation at autopsy is probable in a high per cent of cases

There is another diastolic murmur the meaning of which is purely dependent upon etiology A Flint murmur can not be differentiated by clinical signs alone from the murmur produced by stenosis of the mitral valve The state of the matter is this, so far as clinical signs are concerned a diastolic murmur suggesting aortic insufficiency, a presystolic murmur inside the apex suggesting mitral stenosis In interpretation of these facts the important considerations are the age of the patient and whether there is a history of rheumatism, or of syphilis If the patient is under forty years of age and there is a history of rheumatism then these signs point to rheumatic endocarditis of two valves—aortic insufficiency and mitral stenosis If the patient is past fifty, with no history of rheumatic infection, but a history of lues, then the probability is that the aortic valve alone is involved and the presystolic murmur is a Flint murmur

Without going more into details it seems fairly evident that with murmurs as with arrhythmias the significance of these abnormal sounds is wholly lacking until we interpret them in the light of some infection or abnormal constitutional state Diagnosis is impossible until this is accomplished

But every problem relating to the heart comes finally to the myocardium Murmurs are relatively unimportant, arrhythmias are only significant as an index of the state of the heart muscle In the presence of definite symptoms (marked dyspnea or precordial oppression on exertion, anginal attacks, orthnopea, dependent edema) of heart incompetence even when there is no definite physical sign then there is but seldom any hesitation in arriving at a correct interpretation. But the interpretation of these symptoms suggestive of an over-taxed heart is never made on the symptoms alone, other facts come into consideration A young woman who complains of breathlessness and palpitation, and is obviously restless and has a visible goiter makes a wholly different clinical impression from the middle aged woman with the same symptoms, who is over weight, and has no goiter The heart muscle in both cases looks much alike under the microscope, both may show degenerative changes One patient suffers from Graves disease, the other from arterio-sclerosis and hypertension We think of the disease as a whole and do not focus attention on the heart to the exclusion of the rest of the picture The mere fact that myocarditis due to various causes has the same general character of lesions is inadequate in clincal medicine Myocarditis consequent to a septic infection and myocarditis due to recent diphtheria may produce the same symptoms and physical signs (tachycardia, and apical systolic murmurs, possibly enlargement) and there is nothing characteristic in either myocardial lesion, but in one case the effect of digitalis is notoriously dangerous and in the other it may be beneficial

The commonest form of heart disease is chronic fibrous myocarditis Its symptoms in early stages are variable Indeed the disease is well advanced before there are symptoms A tendency to fatigue, vague digestive disorder are early com-

should create and promulgate procedures to increase the accurate knowledge of heart disease.

The proposition before the physicians of this Society and the physicians of the State appears to be somewhat as follows We know something of the diseases of the heart and how they are caused To make this knowledge effective is the responsibility of the medical societies and of the profession There must be a campaign for the better information of the profession and of the public It must and should be a campaign of frankness and hope The difficulties of the problem are not simple but are interwoven in the very fabric of the social organization They are not insuperable and, therefore, it is incumbent upon us to do our part with enthusiasm, always remembering that only prolonged and united effort can accomplish the desired result

---

THE CLINICAL SIGNS OF HEART DISEASE WITH PARTICULAR REFERENCE TO ETIOLOGY*

By NELLIS B. FOSTER, M D, NEW YORK, N Y

IT is now generally recognized that the character of the lesion in a diseased heart usually points to the etiological factor which induced the disorder One illustration is sufficient to disclose the general force of this statement Lesions of the mitral valve result from systematic infections and those infections are most commonly rheumatic In extreme instances diagnosis as to whether there is or is not a valve lesion will depend on whether there is a history of an infection which might have induced the lesion in question We are prone to be skeptical about the importance of apical systolic murmurs when a young person seems in sound health and when there is no history of rheumatic fever or of an infection prone to injure the mitral valve On the other hand we are fully justified by experience in being seriously concerned if a young man who has had rheumatic fever develops symptoms or signs referable to his heart and this is true even though at an early stage physical examination may fail to disclose either murmurs or arrhythmias

It is evident then, I think, that in the study of a case the diagnosis of heart disease and the character of the lesion are intimately related to etiology

The relation between etiology and the character of a lesion as evidenced in clinical signs is very well illustrated in the commoner arrhythmias Take auricular fibrillation for an example This arrhythmia in a younger patient usually indicates mitral stenosis and myocarditis and the probability is that a rheumatic infection in the past induced these lesions On the other hand, if the patient is over fifty years of age the lesion is probably myocardial fibrosis secondary to arteriosclerosis The physical signs detectable in examination of the heart may be essentially the same in both cases i e, some enlargement, poor muscle tone, and a mitral systolic murmur Pulsus alterans is a less common disorder than fibrillation and is almost always found in older patients Besides indicating an advanced degree of myocardial degeneration, which is usually fibrous in character, this lesion is most often a result of arterio-sclerosis and almost never due to rheumatic myocarditis This difference in significance in respect to age is equally true of other abnormalities in the heart action, of flutter, of delayed conduction, etc, only it must be stated that some of these abnormalities are not so often seen in youth as in age, the degeneration of the senile myocardium, secondary to arterial disease, being particularly prone to produce defects in the conduction system

While heart block is not unknown in young persons it is commonly a disorder of age referable to advanced myocardial fibrosis in definite areas When block occurs in a younger person its cause is an immediate subject for inquiry, since gummata and even tumors located in the conduction path may produce this phenomenon

It would be easily possible to extend the examples of differences of interpretation of heart action depending largely on the age of the patient but the point to which I wish to call attention is that these varied interpretations are essentially different diagnoses The diagnosis in a case is the basic disease, in one case it may be rheumatic infection, or diphtheria, in another, senile atheroma, the heart disorder is only a symptom, though it may be the only symptom It is a key to unlock the larger problem

Not many years ago mitral insufficiency was regarded as the most common of the lesions of the heart valves It headed the column in all standard texts on the heart Pathologists were kindly but the autopsy too often failed to give any satisfactory evidence in support of the clinical diagnosis of valvular disease. Too often it seemed the sole detectable lesion was purely myocardial and myocardial lesions lacked the visible definiteness that we looked for in the scarring of a valve Repetition of these experiences and a

*Read at the Annual Meeting of the Medical Society of the State of New York, at Albany, N Y, May 23, 1928

respect to arterio-sclerosis Syphilis can naturally be prevented whenever society chooses to subject itself to the necessary regulatory measures Meanwhile the value of remedial treatment although it has been tried extensively is by no means clear The effect of treatment studied with sufficient accuracy and reported with sufficient detail has not yet been ascertained and reported in a sufficient number of cases to serve as a basis for action.

In the case of rheumatic fever the hope of *prevention* is heard with less insistence than formerly The excision of the tonsils and the elimination of so called focal infections has not been attended by results as conclusive as were anticipated only a few years ago This chapter requires closer and more detailed study

It is possible now to make the statement that in the past generation a great gain has been made —even if the problem is less simple than was formerly taught. Its very complexity has made it possible to see ways of approach to the solution of many of the component problems which are now known to be involved To solve them means that the lessons which have been learned and which in barest outline have been enumerated, must serve to point the way to future investigations Cases must be distinguished according to their kind, more detail must be reported, groups of cases must be studied according to etiology, according to age, according to course The effect of treatment must become known What relation disease of the tonsils and the teeth bear to diseases of the heart must become firmly established

If aid is to come from closer classification, closer study, fuller reporting of the cases, the labor and cooperation of every physician is essential so as to insure progress in understanding the nature of the problem of the heart diseases, to the amelioration of which your Committee has directed its energy

MORTALITY OF HEART DISEASE IN NEW YORK STATE

By ROBERT H HALSEY, M D., NEW YORK, N Y.

THE SPECIAL COMMITTEE of the New York State Society, working on the Study of Heart Disease in the State of New York during the past two years, has brought out some information of particular interest to all interested in heart work, and particularly to heart work done in the clinic and the statistical tabulation of the work done in the clinic

All statistical work depends on the use of the International List of the Causes of Death Under this List, heart diseases comprise a group of four main headings—pericarditis, endo- and myo-carditis, acute, angina pectoris, and other forms of heart disease Other Forms of Heart Disease, as shown in Chart XI (page 47 of the Report), accounts for 88 5% of all the deaths charged to heart disease. In the United States as a whole they account for 89 4% That is, a little under 90% of all deaths due to heart disease are accounted for under the title "Other Forms of Heart Disease" From Chart XI, it is seen that angina pectoris accounts for only 7 4% of the deaths from heart disease and endo- and myo-carditis account for 3 8%, which makes the two amount to 11.2%

Chart I (page 21 of the Report) is made a logarithmic table and shows the curves of heart diseases, together with six other diseases of a kindred type and makes it possible to compare their rates from year to year In this table you find the curves of pericarditis, endo- and myo-carditis acute, and acute articular rheumatism show a downward direction in the last few years, but angina pectoris and other diseases of the heart show an upward tendency Thus in one group the number of deaths is decreasing, while in the other it is increasing

If we compare heart deaths by age groups with all deaths and with the population, we can construct curves, as shown in Chart VI (page 37 of the Report) These curves are so constructed that the horizontal lines cut them at 25, 50, 75,

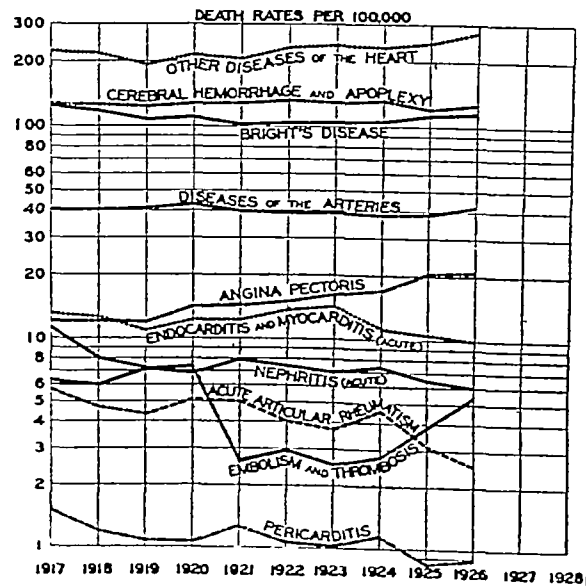

CHART I

Diseases of the Heart and Allied Causes of Death—New York State (Exclusive of New York City) 1917-1926

plaints or possible arrhythmias which occur in attacks Only when there is marked degeneration of the heart muscle do we observe the definite signs and symptoms of cardiac incompetence such as edema, albuminuria, and dyspnea Fibrotic degeneration may be circumscribed or diffuse, but in other respects the lesion is in no way characteristic of the cause which produced it The possible causes are numerous, various infections, such as influenza, rheumatic fever, and sepsis, induce primarily acute myocarditis and this is followed by fibrosis But the most common cause of this type of myocardial degeneration is arterio-sclerosis We are accustomed to think of coronary sclerosis as a cause for a definite clinical syndrome and when the patient survives a cardiac infarction we expect to discover, sooner or later, some changes in myocardial function But the large group of cases of disease of the heart muscle occurring in middle life are not of this class The onset is insidious, the course only seldom marked by angina, is gradually and relentlessly downward In many instances there is vascular hypertension and from this fact we infer arterio-sclerosis In yet another group while the blood pressure is not elevated, the state of the arteries and veins in the fundus of the eye indicates arterio-sclerosis and the probability that there has been vascular hypertension at some period in the past There is finally a small group of varied causation, mild chronic nephritis, untreated thyrotoxicosis, severe cases of paroxysmal tachycardia, etc There is no intention of enumerating all the possible causes of myocardial degeneration but rather to point out that there always is a cause and that this cause is essentially the major disease, the heart disorder but a consequence even when all symptoms are cardiac To ignore the larger conception of a patient's ailment is scientifically inaccurate and clinically superficial

ON THE REASONS FOR FURTHER STATISTICAL ANALYSES OF THE HEART DISEASES *

By ALFRED E COHN, M D, NEW YORK, N Y
From the Hospital of the Rockefeller Institute for Medical Research, New York.

THE remarks I am to make are not designed to be in the nature of a paper but rather as comment on and to give emphasis to the matters to which Doctor Halsey has directed attention.

The older accounts of heart disease discussed the general subject of heart disease under headings similar to those which are now current. There were among others chapters on etiology, on pathological anatomy, on the course of the disease and on treatment In spite of this it is clear that a change is taking place in the current comprehension of this subject There is something new —something strikingly new in the situation In the end we shall be speaking no longer of heart disease but of *diseases of the heart*

In the books of a generation ago the causes of heart disease were given as rheumatic fever, scarlet fever, typhoid fever, arterio-sclerosis, lead and tobacco poisoning, and in connection with these, other causes as well were mentioned The same causes are given still, but certain ones have been elevated into a prominence which they did not formerly possess, we speak of three outstanding ones—(1) rheumatic fever and all the subailments associated with this disease, (2) syphilis, (3) arterio-sclerosis By arterio-sclerosis is meant not a specific disease but a group of abnormalities probably analyzable into a number of distinct parts There is arterial hypertension, there are alterations in the anatomy of the arteries (probably several distinguishable varieties) and there is the structural result of the process of aging

The most important point is that there is recognized first and foremost the fact that there are these many different "causes" for what is called heart disease But the matter does not end here. Each one of these causes carries with it definite inferences—relative (1) to its age incidence, (2) to its pathological anatomy, (3) its course and (4) the treatment of each kind Rheumatism affects individuals predominantly in the second decade, syphilis in the fourth and fifth ones, the arterio-sclerotic obviously later still Not only do these various causes affect individuals at different periods of the life span, but each occupies an appropriate duration, both before the disease becomes manifest and also afterwards between the time the first symptoms begin and its termination in death On account of the differences in age incidence and of the duration of each disease, the economic implications naturally vary With each cause, the pathological anatomy furthermore varies It is now known that the cardiac lesions in rheumatic fever, in syphilis and in arterio-sclerosis (and its sub-divisions) also vary There are many points about the onset and progress and healing of each one of these about which knowledge is lacking but is desirable

There follow from these considerations further ones having to do with therapy Obviously the treatment of rheumatic fever, syphilis, arterial degeneration and senescence must differ Although it is possible to speak of efforts to prevent rheumatic fever, it is not possible to do so in

* Read at the Annual Meeting of the Medical Society of the State of New York at Albany, N Y, May 23, 1928.

(page 75 of the Report) These headings will be—chronic myocarditis, chronic endocarditis, valvular disease of the heart, mitral regurgitation, mitral stenosis, cardiac insufficiency, diseases of the aorta, cardiac hypertrophy and dilatation, cardio-renal, and other diseases of the heart. Surveying these names, we find that we have a number of names applied to the muscle of the heart and a number applied to valves of

TABLE 1-A

Other Diseases of the Heart—Number of Deaths by Broad Age Groups and Percentage of Deaths from each Type—New York State (Exclusive of New York City)

the heart, but in no case do we have an idea of the actual etiological process causing the condition That is, we know what the anatomical change has been, what part of the heart has been affected and how its functional capacity has been involved, but we know nothing of the cause of that damage That is, as now arranged, the International List of the Causes of Death gives no etiological factor Looking at the Table IA these various groups are arranged by age to show percentages in the various groups If we look at the figures after All Ages in 1922, we find that chronic myocarditis accounts for 34% of all the deaths and valvular diseases account for 23% Five years later in 1926, valvular disease accounts for only 15%, while chronic myocarditis accounts for over 48% Percentages under the other headings have remained practically stationary Thus we may infer that during that five years, some influence has caused physicians to sign their certificates more frequently with the muscle disease instead of the valvular disease

If now the method of grouping is made to depend upon the probable etiological factor, the deaths may be re-arranged in the following way

Assume that the damage to the heart before 40 years of age is due to the virus of rheumatism and that some of the heart disease at 40 is due to syphilis, and after 40, the damage to the heart is due to arterio-sclerotic or senescent changes Re-arranging the figures in the table on this assumption, we have the following

Chronic myocarditis—under 40, rheumatic, over 40, senescent

Chronic endocarditis—under 40, rheumatic, over 40, senescent

Valvular diseases—under 40, rheumatic, over 40, senescent

Mitral regurgitation—under 40, rheumatic, over 40, senescent

Mitral stenosis—all ages, rheumatic

Cardiac insufficiency—under 40, rheumatic, over 40, senescent

Diseases of the aorta—under 60, syphilitic, over 60, senescent

Cardiac hypertrophy and dilatation—under 40, rheumatic, over 40, senescent

Cardiorenal diseases—all ages, senescent.

Other diseases of the heart—under 40, rheumatic, over 40, senescent.

This will make the simplified Chart III (page 83 of the Report)

From our review we may infer that under 40 years of age rheumatism accounts for most of the heart disease syphilis for some of the damage a little before and a little after 40 years of age, and arterio-sclerotic, or senescent changes for the deaths after 40 That is, arterio-sclerosis, or

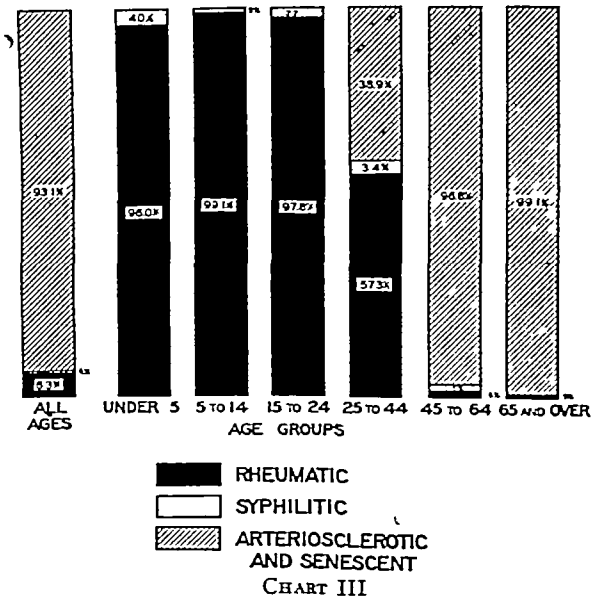

CHART III

Redistribution and Reclassification of Heart Disease Deaths by Assumed Etiological Causes—New York State (Exclusive of New York City) 1926

and 100%, and in this way it can be determined at what age group the Population, All Deaths, and Heart Disease Deaths occur for the same proportion Thus we see that the 50% line cuts the population curve at age 30—that is, half the population are under age 30 and half over age 30 In a similar way we see 50% of All Deaths occur under age 60 and 50% over Of Heart Disease we see that 50% of All Deaths occur under age 70 It is also to be noted that 10% of deaths from Heart Disease occur under age 40—that is, 90% of the deaths from Heart Disease occur after age 40

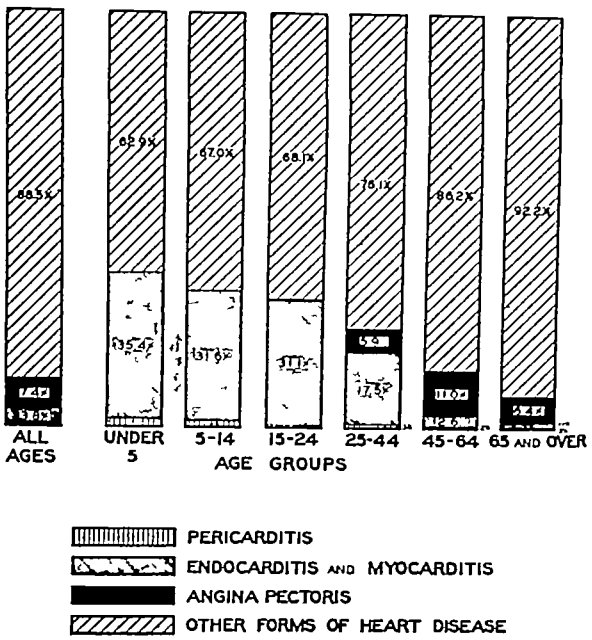

CHART XI

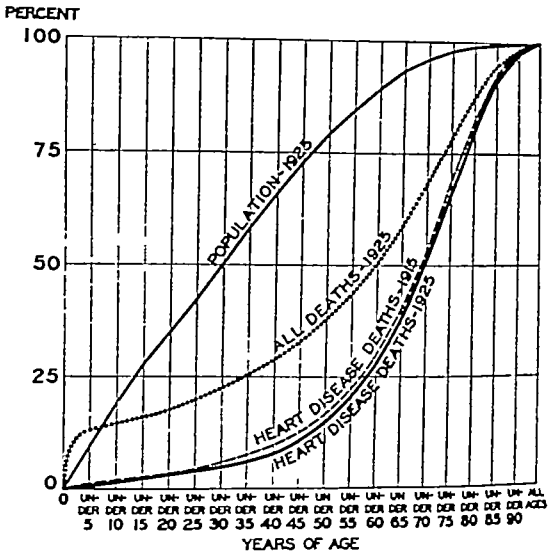
Analysis of Heart Disease—Deaths by Broad Age Groups New York State (Exclusive of New York City) 1925

Chart VA and VB (pages 30 and 31 of the Report), the curve of heart disease, being the sum of the four diseases is compared with six other leading causes of death In these curves we see that in 1915 and 1925 the peak of heart deaths occurred at age 70, that it is by far the highest curve and that since 1915 the peak has gone up above the 2,000 horizontal line We also see that the tuberculosis curve reaches its peak in 1915 in the age groups 20-25, and that in 1925 it had flattened down considerably as compared with 1915, as has the curve for pneumonia The other diseases, cancer, nephritis and cerebral hemorrhage, all show an increase in 1925 over the curve of 1915

If now we turn to the "Analysis of Other Diseases of the Heart" (page 75 of the Report), and instead of following the subdivisions of the group as used in the International List, the certificates



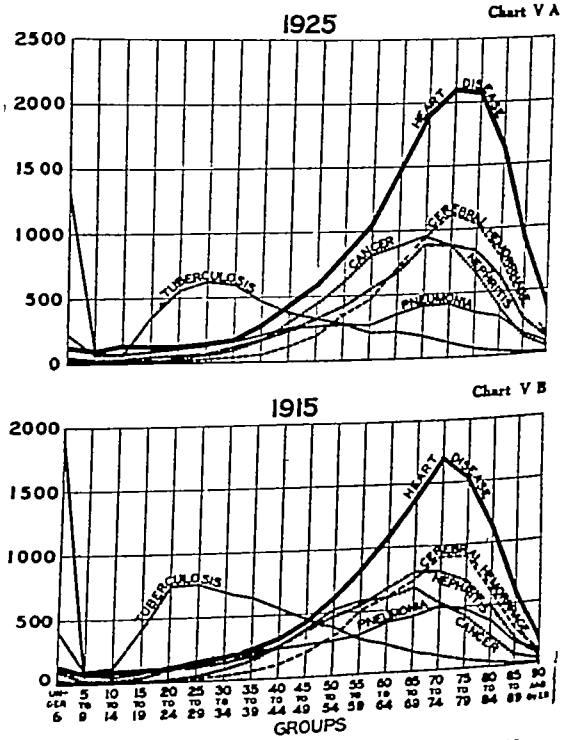


CHART VI-A

of death as recorded in the Bureau of Vital Statistics are allowed to classify themselves, by arranging the certificates according to headings having the greatest number of certificates, ten main groups are obtained as shown in Table IA

Deaths from Six Leading Causes by Age Groups—Ve York State (Exclusive of New York City)

palpate deep in the suprasternal notch an adenoma may be discovered. Then a review of the history of such case may possibly bring out evidence of hyperthyroidism. This method of palpating for an adenoma has been stressed by Doctor Libman

Relative to the early signs of heart involvement in rheumatic fever, I wish to call attention to the diastolic murmur along the left border of the sternum indicating aortic involvement Sometimes the earliest sign is found there

This point is not fully appreciated because of the emphasis of mitral involvement in rheumatic heart disease

Discussion by Dr Harlow Brooks I have been asked to confine my remarks chiefly if not exclusively to the question of a consideration of Etiology No more acceptable subject could have been assigned to me, for in my opinion the most important thing to be now considered in the classification of cardiac disease is this subject of etiology I can not conceive it possible to adequately consider treatment in any cardiac case without falling back primarily on a known or tentative evaluation of etiology The heart is no longer to be considered as a simple mechanical device, though it is never well for us to forget that it is such, to a very considerable degree, and we can never safely ignore the teachings of the elder Austin Flint, of Janeway, and this school of clinicians A knowledge, or at least a theoretical appraisal of etiology seems to me primitively essential to the outlining of any course of treatment.

It is for example, a very serious therapeutic error to treat a case of fatty infiltration of the heart as one would one of rheumatic myocarditis An appraisal of the presumable etiology directs at once the treatment along certain definite lines, without which one can only treat cardiac disease in a discursive or mechanical way, or worst of all by the rule of thumb, which directs in a certain association of symptoms that a certain drug or course of management be given

So keenly do I feel on this point that I would even criticize the projected new nomenclature for cardiac disease in that it insufficiently stresses this point. It is as yet quite impossible however, to define the basic pathology in some cases, much less frequently now than ever before Even if one may not be able to accurately determine the pathology present in any case, an acceptance of the presumable etiology is certain to direct therapeutics along such channels as will meet with little or no disaster in the case.

It is quite impossible of course to utilize the worth which appreciation of etiology brings unless one associates etiology with pathology, proven or presumptive, and I have been particularly appreciative of Dr Rothschild's paper today because he has emphasized that next most essential consideration Knowing the etiology, we may safely assume the pathology if we are unable to define it accurately

This point in particular has led me to feel that some criticism should be directed against the proposed nomenclature because it does not sufficiently elaborate this problem It seems to me quite unsatisfactory that in our delineation of syphilis of the heart no accounting of syphilitic myocarditis or even of gumma has been noted, nor do I find reference to the deposit of the Ashoff bodies in the heart in rheumatism These are of course minor defects I find also no notation of parasitic disease of the heart—this is a very important condition in comparative medicine, notably among the ruminants, it is of course rare in man, but it should certainly be included for the sake of full accuracy at least.

It seems also to me that more consideration should be given to the cardiac disturbances in the numerous endocrine disorders, I find noted only those of thyroid disturbances, but nothing of the interesting disturbances which develop during the involutional syndrome of menopause Certainly worst of all we find the archaic term of "Effort Syndrome," by which I infer is meant the very definite disorder of Neurocirculatory Asthenia, which, by the way, I believe is a term coined by Rothschild and Oppenheimer That this condition is not the result of effort though in some cases the symptoms and clinical picture become most evident after effort, was long ago recognized by Wier Mitchel, by the elder DaCosta, and by other writers in the days of our own Civil War

Brown atrophy and amyloid disease appear also to have been overlooked A recognition of tubercular myocarditis should certainly be also included It appears to me also that the changes of the heart in old age present a clinical and pathological picture quite definite enough to merit inclusion—certainly it is more deserved than the term "Potential Disease" which obviously should, in the mind of the practitioner, include all cases in which no definite cardiac disease can be identified. Would it not be much better to revert to our army days with a diagnosis of "Cardiac Disease, Not Yet Diagnosed" or preferably not yet classified, in such instances?

If we are to consider the heart in Hypertension, ought we not also to consider the rather clear picture presented in hypotension, at least those instances in which this condition does not appear to be a definite disease result, but a constitutional characteristic or peculiarity—certainly recognized by the athletic trainer, or the military medical man

I can not express too fully my appreciation of the effort which has been made and it is particularly evident in this well organized meeting, to more clearly express our knowledge and our inquiries concerning cardiac disease evident in this Nomenclature for Cardiac Diagnosis—it is cer-

senescent changes, accounts for 90%, which is what might be expected with the peak of the deaths occurring at age 70

We may also infer, and this is most important, that before we can know the causes of our deaths from heart disease, we, as physicians, must fill out the death certificates, stating the etiological factor wherever this is possible

The diagnosis of heart disease should contain a statement of the etiological, the anatomical changes in the heart, and the effect of those anatomical changes on the physiological, or functional efficiency of the heart, or the valves

In conclusion, we may say that if we are going to learn anything about the causes of heart deaths, we physicians must make diagnoses giving the causes of death in individual cases so that the statisticians of Boards of Health and Bureaus of Vital Statistics may arrange their machinery to tabulate those facts

DISCUSSIONS

Discussion by Dr T Stuart Hart I want to congratulate the "Committee on the Study of Heart Disease" set up a year ago by the State Society for arranging this interesting meeting and for their valuable report This large published volume not only records many facts of interest which have never before been brought together, but also as a result of a study of these facts, presents certain suggestions of great practical value, which, if put into effect, will definitely add to our scientific knowledge and be of real aid in improving the treatment of the individual patient The State Society is very grateful to this committee for its laborious work and is very proud of its accomplishments

When for one reason or another a patient comes to us to inquire about his heart he almost invariably propounds three questions

First is my heart affected and how?

Second if it is damaged how is it to be treated?

Third and what will be the outcome?

It is obvious that no one of these questions can be satisfactorily answered until one has arrived at a correct diagnosis

Such a diagnosis must include four factors

1 The anatomical condition (apparently we have usually become satisfied with this)

2 The physiological action

3 The functional condition (or the capacity of the heart for work)

4 The underlying cause

All these elements are inter-related, and it is very difficult to reach a correct interpretation of any one of them without considering the others Dr Foster has pointed out the importance of *etiology* in arriving at a correct anatomical diagnosis and the paper on the pathology of the heart by Dr Rothschild has also emphasized this relationship of *etiology* to the kind of lesion which we may expect to find.

I want to stress the importance of a thorough and painstaking history, for only by this means can we secure the information that we need to secure a knowledge of the underlying cause and correlation of the events which have led up to the condition of the patient as we find him Personally I regard the history as the most important single part of the examination

When we use the term "heart disease" it is well to remind ourselves that we are not speaking of a single disease entity as for example typhoid fever, but we are thinking about an organ which may be injured in the course of any one of a number of diseases, such as rheumatism, chorea, gonorreoha, syphilis, arteriosclerosis, the changes incident to advancing years, etc, etc.

Unless, therefore, in every case we search for and keep in mind the *underlying cause* we will not only fall short of scientific accuracy, but will fail to give our patient the kind of intelligent treatment to which he is entitled

When we find a patient with a large spleen our attention is of course engaged not so much with the spleen as the cause of the enlargement such as malaria or typhoid fever To-day no physician would treat a case of pneumococcus lobar pneumonia in the same manner as he would a case of pulmonary tuberculosis merely because the lesion in both cases is localized in the lungs. Is it logical to treat alike rheumatism, chorea, syphilis and degenerative changes merely because they have damaged the heart?

Unless we discover and record the *causal factor* we cannot satisfactorily answer any one of our patient's 3 questions

How is my heart affected?

How is it to be treated?

What will be the outcome?

Discussion by Dr Edward C Reifenstein It seems to me that Doctor Foster's statement that the cause is the major disease, is the keynote of the situation

Auricular fibrillation associated with toxic adenoma of the thyroid is an example.

Patients with rheumatic heart disease, mitral stenosis, may have auricular fibrillation Patients with arterio sclerotic heart disease, fibrous myocarditis, may have auricular fibrillation.

In another group you will find fibrillation without other evidence of heart disease If one will

est part of our therapeutics is concerned with correcting the functional disturbances of the circulation which arise from the disease We give digitalis to correct the congestive failure, or we give nitroglycerine to relieve the anginal syndrome or morphine or other appropriate drugs, but our treatment is incomplete unless we also include an attempt to check the progress of the causative factor of the heart disease, if this is yet active. In its clinical application the use of this complete cardiac nomenclature will greatly broaden our view and lead to a better conception of what is the matter with the patient and what steps should be taken to treat him

Discussion by Dr J H Bainton Among the many charts on display in the cardiac exhibit there are two which seem to carry eloquent messages on this subject The first states that the diagnosis of heart disease is complete only when four factors have been determined 1—the etiology, 2—the anatomical, structural or pathological lesion, 3—the physiological alternation, 4—the ability of the patient to carry on According to the other chart there are practically no statistics available which give us any information about the mortality from heart disease in terms of etiology To my way of thinking these two charts emphasize the most important topics of this whole investigation

The point has been stressed that heart disease is not an entity, but rather the product of any one of many causes It is just as logical to make a diagnosis of lung disease without stating its etiology as it is to speak of heart disease without including its causative factor When we say "pulmonary tuberculosis" we give the site, the cause and the nature of the condition, and even then we are not satisfied until it has been decided as to whether or not the infection is active, and if active what is the degree of severity With heart disease, however, it is seldom that any attempt is made to follow the same plan.

Pneumonia is another disease of the lung in which there is an admirable, though still imperfect refinement in etiological diagnosis Nearly every hospital in this state can give not only the number of cases of pneumonia treated during the past year, but also the number of types I, II, III, and IV, and at the same time scarcely one of these hospitals can show the etiological factors in their cases of heart disease

Until it becomes the custom to speak of heart disease in terms of etiology, it is quite apparent that there can be practically no progress in prevention which, after all, is the main objective.

The other three factors in the diagnosis, the anatomical lesion, the physiological alteration and the functional capacity of the individual are just as important, but we have time only to mention them in passing

It must be acknowledged that every one who attempts to treat diseases of the heart, unconsciously or consciously has these four factors in mind, he does want to know, what has caused the heart disease, what is the pathological and anatomical change; how far from normal in physiological function is the imperfect organ, and what are the limitations imposed on an individual by reason of his heart disease. But while he thinks in these terms, he seldom talks in these terms, nor does he write them into the records, and as a result vital statistics give us no information and hospital chart rooms are eloquently silent on these essential data

If we can consider the diagnosis complete only with inclusion of these four factors and if we insist on this diagnosis being recorded in full, we will be at least in a logical position in a campaign for the care and prevention of heart disease

Discussion by Dr Ward J MacNeal I wish first to express an appreciation of the work of the Committee on Heart Disease of the Medical Society of the State of New York in arranging such an exhibit and such a symposium on this subject It should help toward a more scientific nomenclature of cardiac disorders

The ideal understanding of a disease condition includes adequate knowledge of causative factors, structural alteration and functional readjustment or deficiency Heart diseases still present obscurity in respect to etiology One feels quite confident about syphilis, less certain about rheumatism and quite in doubt in regard to arteriosclerosis, which is in itself in the category of structural alterations

Infectious diseases affect the heart almost exclusively by way of the blood stream The demand for restless activity of the heart is a complicating circumstance of importance. Prolonged rest for this organ is out of the question Often enough the acute injury is very serious without receiving much attention at the time. Cardiac failure following diphtheria and yellow fever are classical examples How is the heart affected in other infectious diseases, particularly the contagious diseases of childhood?

Acute articular rheumatism is undoubtedly a factor in cardiac disease. Yet the essential nature of rheumatism remains relatively obscure and one finds so-called rheumatic lesions of heart muscle and heart valves in individuals without any history of joint inflammations Reliance on the Aschoff body is, in a measure, based upon faith rather than knowledge

The papers presented in this symposium have exposed our shortcomings and have pointed the way to progress and improvement

tainly a vast improvement from the standpoint of the clinician on anything which has ever before been given us The last word has not yet been said nor can it be, perhaps, until we have a more certain knowledge of the effects of nervous and even of psychic states on cardiac action and pathology

In cardio-circulatory disease one must primarily recall physiology He must diagnose and mentally visualize in terms of pathology He must treat from a basis of etiology and of mechanics

Discussion by Dr E Libman The name "subacute bacterial endocarditis" of which I have made use, was meant to apply to those cases of endocarditis of longer duration which were definitely due to known organisms The idea was kept in mind that if rheumatic fever were found to be due to a type of bacteria, a modification in nomenclature would be necessary

Rheumatic fever may occur as an independent condition or as an intercurrent or terminal invasion or as part of a mixed infection Rheumatic endocarditis may be entirely latent Tricuspid involvement is very frequent Recent studies in rheumatic inflammation of the pulmonary valve, the main trunk of the pulmonary arteries and the smaller branches are of great interest They may explain some cases of cyanosis in valvular disease, dilatation of the pulmonary artery, hemoptysis, etc The clinical picture described by Ayerza may well be due at times to rheumatic pulmonary arteritis

Pichon has emphasized the occurrence of the rapidly recurrent, at times practically continuous attacks of rheumatic endocarditis Epistaxis is a most important symptom of rheumatic infection, as are abdominal manifestations, such as pain, diarrhoea and distension

Secondary fibrosis and calcification often play a most important role in the development of valvular defects of rheumatic origin—and probably are significant in the later history of rheumatic disease of the arteries Such fibrosis and calcification, particularly in specially constituted individuals, occur wherever there is strain This is very well seen in cases of bicuspid aortic valve

The murmurs in rheumatic mitral disease may be first heard over the pulmonary artery and left border of the sternum These positions should always be carefully watched

Scarlet fever may cause a remarkable thickening of the mitral valve that is characteristic There is a translucent thickening at the free margin, and a white opaque thickening further up The auscultatory signs consist of a sharp first sound followed by a systolic murmur

In the prevention of subacute bacterial endocarditis stress should be laid upon general building up, and ridding the patient of focal infections In the cases in which there appears to be a real risk in removing the tonsils, as in decompensated cases, there is not much danger in leaving them The disease has little tendency to occur in patients whose hearts show marked insufficiency or who are fibrillating

Discussion by Dr Harold E B Pardee My first comment upon the work of this committee is that I feel that the effort, the imagination and the initiative of the chairman, Dr Halsey, has been a tremendous factor in the accomplishment of what has been done The State Medical Society is to be congratulated on having found one who was able to push forward this work in such a way, and to produce such an important series of observations

It is evident from the report which has been placed before you that our recent advances in the knowledge of heart disease has carried the ability to diagnose the state of the heart far beyond the current methods of nomenclature of heart disease. After examining the heart by the various methods available, we are able to diagnose its pathological condition, the causes which have led up to this, the abnormal physiological mechanisms which are present, and the functional capacity of the heart, and yet we are unable to express these facts in the usually accepted systems of cardiac diagnosis A part of the report of this committee consists of a modernized nomenclature of cardiac disease which will make it possible for you to do this I feel that it will be worth your while to examine this nomenclature carefully and to realize how much is brought out by its titles, which is helpful in promoting clear thinking in regard to your patients and the completeness of your cardiac diagnosis I would refer you especially to a new term which has been introduced, fibrosis of the myocardium This is intended to express the pathological condition which has been for many years called chronic myocarditis, but to exclude many of the indefinite and vague symptom complexes which have often been given this diagnosis

I believe also that a careful reading of the criteria for cardiac diagnosis, which has been devised by the New York Heart Association and adopted by this committee of your society, will amply repay you This is an effort to describe the physical signs upon which a dependable cardiac diagnosis may rest and its value is in concentrating the thought of all of us along definite lines, emphasizing the important diagnostic features, so that different men will be more liable to make the same diagnosis when examining a given patient.

In planning the treatment of a cardiac patient, it is necessary for us to consider carefully all four of the main titles of the cardiac nomenclature. The importance of the pathological section of the diagnosis is chiefly that it gives us an idea of the handicap under which the heart is laboring We can do very little to directly attack the pathological condition within the heart. The great-

agonizing colic, mental confusion, impaired vision, pruritus, etc, it is a simple matter to ascertain the action of the metals on the living economy Thus far such methods have not been presented and as a result it is necessary to draw our conclusions from the end results seen in the human economy

Experience has taught us that all dynamite is potentially explosive Therefore its sale and transportation, and use is controlled, typhoid organisms are all potentially dangerous but not always producing typhoid fever, bacterial count in milk represents carelessness in the production of milk, therefore milk is controlled. Thus experience has taught us to be on our guard for those elements which destroy health and happiness which in turn regulate our industrial and economic relations

It is interesting to cite our changing food habits during the past century The annual per capita consumption of sugar in 1823 was 9 pounds, equivalent to 44 calories per day, and 1924 more than 110 pounds represents the corresponding value with an average daily consumption of 547 calories Little thought is necessary to observe that our daily habits have materially changed in a century and that we are suffering from a malady of "carbohydratism." This enormous consumption of carbohydrate is a national dietary fault due to overindulgence in sugars In 1926 a Depart of Commerce Survey of 80 per cent of the candy makers of the nation produced 1,083,399,754 pounds This is equivalent to 9 pounds for every man, woman, and infant

This briefly gives a dietary background of studies carried out by us at the New York Skin and Cancer Hospital leading to the relations of metals as *causative* or *fulminative* factors in the production of industrial dermatoses and intoxications

Much has been written on the cumulative action of lead and its disastrous results has brought about a call to arms to eliminate this condition

Early Greek, Latin, and Arabian physicians knew that lead would produce colic and Dioscordies early described the colic and paralysis Pliny and Gerber also wrote of its action The widespread use of lead as material for cooking vessels caused a notorious outbreak of lead poisoning "Colic of Poitou" was a term that originated through the adding of lead to promote fermentation of the wine in France. Tanquerel des Planches at the Hospital of La Charite in Paris between 1831-9 saw 1217 cases of lead colic, arthralgia in 755 cases, paralysis in 127, and encephalopathy in 72 The action of lead on the gastrointestinal tract, the kidneys, the spinal cord, and peripheral nerves, the brain, the blood the bone marrow, the spleen can only be appreciated by detailed study and no one can raise question that industrially and from a health point of view the element is a great health hazard The Harvard Lead Studies and that group of workers deserve much credit for the monumental study carried out by them Our interest in lead came about largely through studies associated with the great menace of the decade—insecticides and our contact with some cases following exposure to lead tetra ethyl It is our contention, in spite of present reports, that lead dust from automobiles will be shown definitely to be injurious in the next era. Our observations have shown us that these deleterious results do not appear even as a chronic effect, but even years later the individual finds it necessary to consult a group of specialists only to find that some insidious metal is at the basis of all these ailments Thus later manifestations makes it desirous to sound the alarm and call the reserve forces to arms in order to prevent these symptoms The *latent* effects of metals attack more individuals than those with the chronic and acute symptoms The occupational interest in lead is varied, and the character of the symptomatology of the condition makes it closely associated with every branch of medicine —neurology, internal medicine, haematology, pathology, preventive medicine, and hygiene.

The use of lead pipes for water supply should be eliminated, and this is well brought out by Wright, Sappington, and Rantoul in "Lead Poisoning from Lead Piped Water Supplies," in which they have made a thorough examination of this situation, covering cities and towns in Massachusetts, in which lead conducted water supplied are studied Their summary is as follows

"A chemical study was made of 102 lead conducted water supplies — city, well, and spring waters—ninety of which were used by a total of 253 persons subjected to clinical investigation

All the waters analyzed contained lead

The lead content was most strikingly related to the carbon dioxide content.

There was no apparent relation between length of pipe and lead content.

Of ninety sources used by the persons studied, thirty-five caused poisoning as determined by certain criteria

Of 253 exposed persons, sixty-three, or 24 9 per cent, were poisoned

Poisoning occurred among fourteen persons ingesting as little as *0 1 mg of lead daily,* over an average period of *eight and one-quarter years*

The incidence of poisoning was distinctly lower in children under 10 years of age than

HEALTH HAZARDS FROM THE INGESTION OF SMALL AMOUNTS OF METALS*

By C N MYERS, PH D, AND BINFORD THRONE, M D, BROOKLYN, N Y
From New York Skin and Cancer Hospital

IT has been aptly said that the next great war is in progress, for it is a conflict between man, bacteria, and insects The battle for the future food supply is in progress and in a few instances man has shown himself the victor Modern means of production, transportation, and distribution have enmeshed the human race in a maze of conflicts from which it is difficult to escape In a discouraging number of cases the enemy has been cutting away the supply lines and displaying a marked indifference to the weapons now at our disposal There are many who recall the days when potato bugs were unusual, when the gypsy tail moth was a myth, when the European corn borer was an unheard of entomological entity, when the codling moth had not yet learned to live on the foliage of our fruit trees, when poliomyelitis, encephalitis, and influenza, B coli, typhoid and diphtheria were epidemologically unrecognized Yet in this space of a few decades all life and its control have met with unusual attacks

It is hardly necessary to more than refer to the excellent control of the milk supply, both in relation to the contagious diseases and bacteria, the shell-fish control, food control, water supply, and sewage disposal Yet, in spite of all the refinements and niceties that lead to our general well-being and security of health in our homes, many menaces loom large on the horizon of our existence

More recently, or at least recognized, metals and their intoxicating action have been noted and it is interesting to quote from the preface of Hamilton's book on Industrial Poisons in which she says

"The sources of our knowledge of industrial poisoning in the United States are neither full nor, for the most part, accurate We lack the sickness insurance system which obtains in all industrial countries in Europe and which brings to light the incidence of illness of all kinds in all groups of workers Nothing takes its place in this country Our private insurance companies sometimes gather important and trustworthy data, but these are never all-inclusive and never can be, they are always restricted to the group of individuals insured in that company The Census reports are of deaths only, not illness, and the death records lose much of their value because of a poor classification of workers, which puts into the same category men doing work of very different degrees of danger, as for instance paper-hangers and painters Trades union records are seldom of value, with the exception of those gathered by the typographical unions which were reviewed carefully by Verrill and found to contain much that was interesting to the statistician"

Since our entrance into the war there has been an enormous increase in the number of cases which should be included in industrial toxicology The combined effect of long exposure, unfavorable sanitary conditions, "genetic faults," artificial modes of living, new attempts to destroy insect, and bacterial enemies, all lead to a more favorable condition for metallic disturbances

There are industrialists who hold up a hand in horror if the possibility of any disturbing substance is mentioned concerning their product. Many may quote literature twenty years old to support their horror They forget life now exists in a new form, its activities travelling at high speed with an ever increasing number of sensitive individuals Economic efficiency is being sought in the face of these undermining influences There is no one prepared to evaluate these loses either in personal comfort or in monetary values Furthermore it is important to consider this problem from many angles chronic and acute poisoning, economic relations, public health at large, domestic happiness and the future effect on succeeding generations

Many pertinent facts could be stated in favor of one angle or another of this problem It is necessary to state only once that as investigators we are "pro" neither one way nor the other except in so far as it brings about changes in health and happiness The operator and the employee concern us only as health hazards Our experience is drawn from the long list of patients at our disposal Our results and conclusions are obtained from the human and not from primary animal experimentation It is our contention that metal poisoning cannot be adequately studied from the animal whose dietary conditions, cutaneous manifastations, neural peripheral responses are quite different from the human Therefore it is questionable as to the value that can be obtained from such an attack. At the present time there is no known method of determining the minimum dose or the minimum exposure which will produce a symptom, nor is there any method of determining either the maximum or minimum period after exposure when this symptom will appear If any experimenter on animals is able to detect

This enormous consumption of carbohydrate is a national dietary fault due to overindulgence in sugars In 1926 a Depart of Commerce Survey of 80 per cent of the candy makers of the nation produced 1,083,399,754 pounds This is equivalent to 9 pounds for every man, woman, and infant.

This briefly gives a dietary background of studies carried out by us at the New York Skin and Cancer Hospital leading to the relations of metals as *causative* or *fulminative* factors in the production of industrial dermatoses and intoxications

Much has been written on the cumulative action of lead and its disastrous results has brought about a call to arms to eliminate this condition

Early Greek, Latin, and Arabian physicians knew that lead would produce colic and Dioscordies early described the colic and paralysis Pliny and Gerber also wrote of its action The widespread use of lead as material for cooking vessels caused a notorious outbreak of lead poisoning "Colic of Poitou" was a term that originated through the adding of lead to promote fermentation of the wine in France. Tanquerel des Planches at the Hospital of La Charite in Paris between 1831-9 saw 1217 cases of lead colic, arthralgia in 755 cases, paralysis in 127, and encephalopathy in 72 The action of lead on the gastrointestinal tract, the kidneys, the spinal cord, and peripheral nerves, the brain, the blood the bone marrow, the spleen can only be appreciated by detailed study and no one can raise question that industrially and from a health point of view the element is a great health hazard The Harvard Lead Studies and that group of workers deserve much credit for the monumental study carried out by them. Our interest in lead came about largely through studies associated with the great menace of the decade—insecticides and our contact with some cases following exposure to lead tetra ethyl It is our contention, in spite of present reports, that lead dust from automobiles will be shown definitely to be injurious in the next era. Our observations have shown us that these deleterious results do not appear even as a chronic effect, but even years later the individual finds it necessary to consult a group of specialists only to find that some insidious metal is at the basis of all these ailments Thus later manifestations makes it desirous to sound the alarm and call the reserve forces to arms in order to prevent these symptoms The *latent* effects of metals attack more individuals than those with the chronic and acute symptoms The occupational interest in lead is varied, and the character of the symptomatology of the condition makes it closely associated with every branch of medicine —neurology, internal medicine, haematology, pathology, preventive medicine, and hygiene

The use of lead pipes for water supply should be eliminated, and this is well brought out by Wright, Sappington, and Rantoul in "Lead Poisoning from Lead Piped Water Supplies," in which they have made a thorough examination of this situation, covering cities and towns in Massachusetts, in which lead conducted water supplied are studied Their summary is as follows

"A chemical study was made of 102 lead conducted water supplies — city, well, and spring waters—ninety of which were used by a total of 253 persons subjected to clinical investigation

All the waters analyzed contained lead

The lead content was most strikingly related to the carbon dioxide content.

There was no apparent relation between length of pipe and lead content.

Of ninety sources used by the persons studied, thirty-five caused poisoning as determined by certain criteria

Of 253 exposed persons, sixty-three, or 24 9 per cent, were poisoned

Poisoning occurred among fourteen persons ingesting as little as *0.1 mg of lead daily*, over an average period of *eight and one-quarter years*

The incidence of poisoning was distinctly lower in children under 10 years of age than

among children from 10 to 20 years old or among adults, and was greater among adults than among children under 20

The duration of exposure, except for very short periods, was not significant in its relation to the incidence of poisoning

The incidence of poisoning was quite uniform among those ingesting varying amounts less than 1 5 mg daily but was much greater as this amount was exceeded

Under almost all conditions of comparison —by age, duration of exposure, amounts of lead ingested daily, and total amounts of lead ingested—women showed a lower incidence of poisoning than did men"

Mercurialism is of interest on account of its varied methods of manifesting its intolerance Salivation, dermatitis, ulcers, jaundice, tremor, gastrointestinal, and skin symptoms prevail Mercury is used in so many ointments that it is not unusual to see this type of skin eruption The hatter's trade is one of the abundant sources of patients in our vicinity In this group exposure to minute quantities of vapor sooner or later present themselves One of the most recent cases to appear at our Clinic was a hatter In general the condition would appear as a generalized eczema but blood examination showed a typical metallic picture and his condition responded to eliminative treatment Discussion of the method of use of the mercury is not of value at this time except to state that absorption takes place through the skin, the mucous membranes, the lungs, and the gastrointestinal tract Warning is also made in regard to the promiscuous spilling of mercury on the floors of laboratories resulting in volatilization and ultimate poisoning The amounts may seem small but the danger exists Several chemists have been able to demonstrate the presence of mercury in the urine Manufacturers of thermometers, furriers, dentists handling amalgams, and even patients with amalgam fillings may occasionally show symptoms, mercury reduction plants (cows pasturing in the vicinity of such plants often show the effects), barometer makers, fire gilding, "constant potential" departments of electrical works, solder used for dry batteries are all common sources of contamination Tremor, salivation, colic, diarrhœa, ulcers, nervous symptoms, sleeplessness, and cutaneous manifestations are some of the more common clinical observations

Investigation has shown that there is a retention of ingested zinc, but the effect on the economy has not been worked out more than superficially In Silesia a form of illness resembling brass founders' ague has been noted The ore in this region contains lead, arsenic, and cadmium and therefore it is difficult to ascribe all of the action to one metal In brass poisoning a complication exists in that it is an alloy of zinc, copper, with varying proportions of lead Tin may also be a constituent with arsenic, phosphorus, antimony and cyanides as impurities

At this time it is important to mention the possibility of copper contamination in the preparation of dairy supplies, as well as in connection with food supplies, in which the containers may be made of copper and plated with various metals, depending upon the purpose for which they are used. Unfortunately on many occasions utensils are used in which the plating has been worn off, and this should be given consideration from the point of view of the ingestion of copper

A recent work of Mallory on copper poisoning is of vital interest. The investigations of Mallory were very thorough and included a great many patients who had been exposed to copper One of the very important experimental findings pointed out by Mallory is that his investigations on liver damage were carried out particularly in the case of sheep at the end of a year after exposure In distilled liquors it was shown that as much as 185 mgs of copper per liter was found This shows the extreme danger involved in the consumption of liquor The Massachusetts Department of Health has found, on the basis of an examination of 798 samples, that 10 8% of them contained copper Mallory points out the danger of copper through the use of apple butter which, in some parts of the country, is made in copper kettles Copper tea and coffee pots are also mentioned It is further stated that after copper powder is sprinkled in melted lard, heated for fifteen minutes, and then filtered out, that copper is found in the lard Cocktail shakers made of copper and brass and lined with silver or tin, shakers at soda water fountains for mixing lemonade and sodas should be excluded from use Brass water pipes in Brookline were so eroded after fifteen or eighteen years that a pin could be thrust through them anywhere, thus showing that the copper was dissolved and carried along with the water In his conclusions it is stated that chronic poisoning with copper caused the symptom complex of hemochromatosis, bronzed diabetes, and pigment cirrhosis It is further stated that copper in spite of its usefulness in so many ways should not come in contact with food or drinks, especially if they contain acids of any sort. This should exclude its use for cooking utensils of any sort, for shakers of cocktails and acid drinks, and for worms of containers in stills

The presence of copper in seafood has been investigated by the United States Public

Health Service, and varying amounts have been found in shellfish from various sources The presence of antimony in rubber tubing through which fluids pass is also a question that has been investigated, but so far as definite knowledge is concerned application has not been made to its regulation

The action of copper on the vitamin content of milk has been thoroughly investigated by Hess, showing definite deleterious changes Furthermore the British Medical Journal of 1924 suggests that in the construction of a pasteurizing plant in which the apparatus is not in good repair or well cared for, there exists a real danger of copper contamination

The widespread use of aluminum either as compounds or utensils exposed to foods and drinks is still questionable Many investigators have carried out animal experiments to prove an assertion one way or another but it is our belief that these results are untenable when applied to the human The only satisfactory method is to make the vital test on the large scale The study of metals in foods cannot be accurately studied on animals nor can it be stated that metals ingested with foods are harmless except in excessive amounts or in cases of hyperacidity The aluminum situation needs illumination clinically and chemically

Before discussing the last element which is responsible for a great many human ailments as well as being one of the important metals from a therapeutic point of view, it is important to briefly discuss the question of the oligodynamics of heavy metals and their salts Falta and Richter, 1921, arranged the metals in the order of their relative oligodynamic activities, and the arrangement was as follows copper, mercury, silver, lead, tin, zinc, aluminum, iron, magnesium, and platinum To further elucidate this point of oligodynamics it is necessary to only consider the placing of a dime in a beaker of distilled water If this metal or coin remains in the water for a period of eight days, the water when examined is found to contain bactericidal properties, showing definitely that the metal has gone into the solution, due to its exposure to distilled water When this solution is tested upon various kinds of bacteria, it is shown that the bacteria cannot live, thus demonstrating the fact that even small quantities of metal will produce marked changes upon protein substances The same condition is applicable to the human being As a result of fifteen years of study in regard to arsenic, both from a therapeutic point of view, as well as from a toxicological point of view some of the salient observations are being reported at this time

Arsenic is one of the most widely distributed elements with which we have occasion to come in contact It is a substance which has the common lot of all common drugs—that it is now praised and now blamed, and its dynamic efficacy on the organism cannot easily be reached by any drug, and still less surpassed One cannot therefore be surprised that it is decried, especially by those physicians who fight shy of all power in a drug, while it is always properly esteemed by those who understand how to make use of such an important power That arsenic was the most terrible poison under all circumstances was the general opinion of the former, and they expressed this without considering that no absolute poison could exist, and that it is precisely these poisons which are our most powerful weapons Therefore, if any one wishes to realize the curative power of arsenic, then he must adhere solely to what observation of the healthy and diseased organism has taught us, and must entirely forget all statements made by important men from a preconceived idea

This leads us to consider a point in which a poison is defined Some substances are extremely poisonous under certain conditions, and under others they are important remedial agents In the definition of poison in its relation to public health it is necessary to express both the quality and the degree of the action resulting from the ingestion of the deleterious substances Old English law defines a poison as a destructive substance administered to, or taken by, a person, and includes not only substances which act on account of their inherent chemical and other properties after ingestion and absorption into the blood, and also mechanical irritants, and specifically tainted fluids In detail, a destructive agent includes substances gaseous, liquid, solid, living or dead, which may injure or destroy life Huseman and Kobert present two other definitions which should be given consideration Huseman—"We define poisons as such inorganic or organic substances as are in part capable of artificial preparation in part existing, ready formed, in the animal or vegetable kingdom, which without being able to reproduce themselves through the chemical nature of their molecules under certain conditions, change in the healthy organism the form, and general relationship of the organic parts, and through annihilation of organs, or destructive of their functions, injure health, or under certain conditions, destroy life"

Kobert adds "Poisons are organic or inorganic unorganized substances originally in the organism itself, or introduced into the organism, either artifically prepared, or ready

formed in nature, which through their chemical properties, under certain conditions, so influence the organs of living beings, that the health of these beings is seriously influenced *temporarily* or *permanently*"

This comment differentiates between the toxic action of arsenic as compared with the highly commendable properties of arsenic as a therapeutic remedy No one can question the favorable action of the Salvarsans in the treatment of syphilis They report the acme of many years of therapeutic research, and also the fact that there was a differentiation between the chemical constitution of arsenic as applied to therapy in comparison with inorganic and pentavalent arsenic preparations, which for the most part produce toxic actions In relation to the Salvarsans the question of toxicity, solubility, and clinical effect were all properly balanced in selecting a drug of satisfactory type Physiologically it is shown that therapeutic differs materially from arsenic in its other forms Arsenic as a pentavalent substance in the form of an insecticide or as a substance in foods, drugs, and drinks behaves quite differently from the element in its best form, such as the Salvarsans

In connection with the subject of metals it should be perfectly evident that the application of metals or their salts for therapeutic measures is a somewhat different condition from that of the contaminating product found in foods, drugs, and drinks There is no question that in some instances even late effect may be observed, when products are administered therapeutically, by the reaction between the invading disease and the therapeutic product. The therapeutic product gives an entirely different aspect than the daily ingestion of contaminated substances The widespread use of insecticides in order to produce more perfect fruits and vegetables, the use of impure ingredients in the preparation of artifically prepared foods offer wide possibilities of contamination It is only necessary to refer to Food and Drug Decisions of the United States Department of Agriculture in this respect to show that excessive amounts of metals have been found

The United States Department of Agriculture, Judgment 1,105, showed an excessive quantity of arsenic in Sodic Aluminic Sulphate, and the decision rendered was that the product was not to be used as a food Decision 6,044 showed the presence of arsenic, copper and zinc which might render the gelatin an article injurious to health Decision 5,958 was similar in nature, relating to gelatin Decision 7,397 was a consent decree of condemnation in which arsenic, copper, mercury, and zinc were contaminating ingredients Decision 8,483 showed excessive amounts of arsenic and copper in gelatin, 8,036 showed arsenic and copper in gelatin, 7,190 showed arsenic, copper, and zinc in improper proportions in gelatin. 7,939 is of especial interest in that it showed 71 parts per million of copper 6 parts per million of arsenic, and 1,237 parts per million of zinc. Decision 11,500 showed excessive quantities of zinc, copper, and arsenic in marshmallow powder Apple chops was another abundant source of contamination, as indicated by Decisions 14,680, 14,681, and 15,395, in which arsenic was the contaminating factor Decision 14,973 relates to the contamination of a carload of celery in which arsenic was present in quantities which might be harmful to health Decision 15,350 relates to the presence of arsenic and lead in apples and pears Decision 10,371 pertains to the adulteration of food colors showing the presence of arsenic in sufficiently large quantities to bring the matter before the Court. Several other cases involving the misbranding of colors have been handed down Decision 1,243 deals with the finding of 12 4 mg of arsenic oxide per kilo in candy Decision 989 showed the presence of 12 parts of arsenic per million in "chocolate Cremolin" Decision 2,406 is of particular interest in that it shows the extremely large amount of arsenic present in the adulteration of confectionery in which 87 mg of arsenous oxide in the shellac scrapings from candy per kilogram were found Decision 2,497 showed the presence of 75 parts per million of arsenic in an adulteration of phosphate which was to be used for food

In previous articles the normal arsenic value has been discussed and stated as not exceeding 30 micromilligrams per one hundred grams of dried specimen The earliest recognition of the ingestion of arsenic in this country probably was the work of Putnam and Hill who were able to trace the arsenic to the wall hangings In their studies 75 per cent of the specimens showed the presence of arsenic The presence of arsenic in Marine Crustaceans and Shellfish has been confirmed by Scandinavian, English, and American investigations A J Jones (1922) in the English Year Book of Pharmacy page 388 states that arsenic to the extent of 6 to 125 parts per million as arsenious oxide was found The report of the Swedish Government on the general question of arsenic poisoning is worth reading by any one interested in this subject Sillig showed the importance of arsenic in soils, vegetables, animal foods and marine algae Endemic arsenicism has been noted in the province of Cordova in which there is an area in which both the ground and the water contain sufficient arsenic to induce chronic arsenic poisoning in man

and in animal Escallops varied between 35 and 85 parts per million (wet), mussels between 36 and 119 parts (wet), cockles 17 and 40 parts, whalks 12 and 40, lobster 36 and 40 whereas in specimen 5 showed as high as 110 parts per million, Norway lobster 29 to 100 parts, prawns 36 to 174, shimp 12 to 40 parts, crabs 36 to 70 parts Three parts per million is equivalent to 1/48 grain of As_2O_3 per pound Thus in the case of prawns there is present 1.2 grain per pound

Chapman examined 16 samples of sea water with an average of 0 33 parts per million or approximately 1/40 grain per gallon Russian caviare contained 5 parts per million To further show the importance of these findings the same authors studied the ingestion of these lobsters by human subjects It was definitely shown that the increase of arsenic in the urine for the 12 hours following the consumption of the lobster was 85 times that of the normal value per gallon, still further increasing during the next 24 hours to 136 times the normal value. These values are mentioned by us for the good reason that it is a well-known observation that some individuals are unable to eat fish and other crustaceans without gastric disturbances as well as conditions of pruritus It has been our policy to avoid the use of fish as much as possible in the diet of our skin patients This furthermore should dissipate the mirage that has appeared in the minds of some that it is impossible for arsenic to reach the human economy, and if it does, no harm can result. The famous beer cases of 1900 have always served to keep the English observers ever alert to the public health menace

Cox, 1925, further enhances our knowledge of the subject by showing that patients fed on a fish diet excrete far more arsenic per liter than average hospital cases In 1922 an interesting situation arose in England in relation to cocoa. Arsenic in cocoa surely is one of the most unexpected sources, yet the Home and Colonial Stores were selling cocoa which contained one-fortieth of a grain of arsenious oxide per pound Rowntree sold a similar product with one-tenth of a grain per pound The arsenic was traced to the potassium carbonate used for the purpose of rendering the cocoa soluble Baking powders, egg powders, self-raising flours, need consideration due to the use of impure acid phosphate Analyses have shown 10 parts per million in egg powders, 6 6 parts in baking powder Self-raising flour contained quantities varying from 0.2 to 2 parts per million The British Royal Commission have recommended 1/100 of a grain of arsenic per gallon, and per pound This amounts to 1 43 parts per million Baking powder with as much as 1/18 grain of arsenic per pound has been found There is a temptation on the part of manufacturers to use inferior and possibly contaminated materials, thus requiring the vigilance of those who guard over food and drug supplies

Two cases of illness resulting from eating Pfefferkuchen made with potassium carbonate have been reported This is closely associated with the English cases Potash is used in the Dutch process of cocoa manufacture, thus directing our attention to chocolate products This is important in its relation to children who eat large quantities of chocolate cookies and chocolate products

In 1921 Cazeneuve reported a fatal outbreak of arsenic poisoning as a result of insecticide. There were *fifteen* deaths which occurred promptly Severe peripheral neuritis and acute arsenic symptoms appeared in the non-fatal cases The poisoning was presumed to have resulted by drinking water in which a soluble arsenic insecticide had found its way Each glass and a half contained more than a grain of the salt The law of 1916 in France forbids the use of soluble arsenicals in agriculture and this episode called forth the efforts of the Academie of Medicine to prevent a recurrence of this laxity Occiphral was the highly toxic arsenical insecticide employed in the vineyards where this series of fatal cases were observed Sir William Willcox, 1922, read a paper before the section of Industrial Diseases expanding on the sources of danger due to arsenic The author states that there has been a large increase in the number of cases of arsenic poisoning since 1908 and he attributes this to the ease with which arsenic is obtained, and the wide use in agricultural and horticultural purposes The use of arsenic as weed killers finds extensive application in England and has given rise to accidental as well as criminal poisoning A sack of sugar absorbed a quantity of the poison from a leaky tin in railroad transit About 60 cases resulted but no deaths In the case of Rex V Bingham, 1911, three fatal cases of arsenical poisoning were the subject of inquiry and these cases were undoubtedly due to liquid weed killer

Wrappers used for bread and other foods have been the source of contamination Blue, purple and green wrappers have been particularly contaminated Occupational arsenic cancer has been reported by O'Donovan In the vicinity of the copper smelting works and tin burning houses of Cornwall, horses and cows commonly lose their hoofs, and have a cancerous affliction of their rumps It deserves

formed in nature, which through their chemical properties, under certain conditions, so influence the organs of living beings, that the health of these beings is seriously influenced *temporarily* or *permanently*"

This comment differentiates between the toxic action of arsenic as compared with the highly commendable properties of arsenic as a therapeutic remedy No one can question the favorable action of the Salvarsans in the treatment of syphilis They report the acme of many years of therapeutic research, and also the fact that there was a differentiation between the chemical constitution of arsenic as applied to therapy in comparison with inorganic and pentavalent arsenic preparations, which for the most part produce toxic actions In relation to the Salvarsans the question of toxicity, solubility, and clinical effect were all properly balanced in selecting a drug of satisfactory type Physiologically it is shown that therapeutic differs materially from arsenic in its other forms Arsenic as a pentavalent substance in the form of an insecticide or as a substance in foods, drugs, and drinks behaves quite differently from the element in its best form, such as the Salvarsans

In connection with the subject of metals it should be perfectly evident that the application of metals or their salts for therapeutic measures is a somewhat different condition from that of the contaminating product found in foods, drugs, and drinks There is no question that in some instances even late effect may be observed, when products are administered therapeutically, by the reaction between the invading disease and the therapeutic product. The therapeutic product gives an entirely different aspect than the daily ingestion of contaminated substances The widespread use of insecticides in order to produce more perfect fruits and vegetables, the use of impure ingredients in the preparation of artifically prepared foods offer wide possibilities of contamination It is only necessary to refer to Food and Drug Decisions of the United States Department of Agriculture in this respect to show that excessive amounts of metals have been found

The United States Department of Agriculture, Judgment 1,105, showed an excessive quantity of arsenic in Sodic Aluminic Sulphate, and the decision rendered was that the product was not to be used as a food Decision 6,044 showed the presence of arsenic, copper and zinc which might render the gelatin an article injurious to health Decision 5,958 was similar in nature, relating to gelatin Decision 7,397 was a consent decree of condemnation in which arsenic, copper, mercury, and zinc were contaminating ingredients Decision 8,483 showed excessive amounts of arsenic and copper in gelatin, 8,036 showed arsenic and copper in gelatin, 7,190 showed arsenic, copper, and zinc in improper proportions in gelatin 7,939 is of especial interest in that it showed 71 parts per million of copper 6 parts per million of arsenic, and 1,237 parts per million of zinc. Decision 11,500 showed excessive quantities of zinc, copper, and arsenic in marshmallow powder Apple chops was another abundant source of contamination, as indicated by Decisions 14,680, 14,681, and 15,395, in which arsenic was the contaminating factor Decision 14,973 relates to the contamination of a carload of celery in which arsenic was present in quantities which might be harmful to health Decision 15,350 relates to the presence of arsenic and lead in apples and pears Decision 10,371 pertains to the adulteration of food colors showing the presence of arsenic in sufficiently large quantities to bring the matter before the Court. Several other cases involving the misbranding of colors have been handed down Decision 1,243 deals with the finding of 12 4 mg of arsenic oxide per kilo in candy Decision 989 showed the presence of 12 parts of arsenic per million in "chocolate Cremolin" Decision 2,406 is of particular interest in that it shows the extremely large amount of arsenic present in the adulteration of confectionery in which 87 mg of arsenous oxide in the shellac scrapings from candy per kilogram were found Decision 2,497 showed the presence of 75 parts per million of arsenic in an adulteration of phosphate which was to be used for food

In previous articles the normal arsenic value has been discussed and stated as not exceeding 30 micromilligrams per one hundred grams of dried specimen The earliest recognition of the ingestion of arsenic in this country probably was the work of Putnam and Hill who were able to trace the arsenic to the wall hangings In their studies 75 per cent of the specimens showed the presence of arsenic The presence of arsenic in Marine Crustaceans and Shellfish has been confirmed by Scandinavian, English, and American investigations A J Jones (1922) in the English Year Book of Pharmacy page 388 states that arsenic to the extent of 6 to 125 parts per million as arsenious oxide was found The report of the Swedish Government on the general question of arsenic poisoning is worth reading by any one interested in this subject Sillig showed the importance of arsenic in soils, vegetables, animal foods and marine algae Endemic arsenicism has been noted in the province of Cordova in which there is an area in which both the ground and the water contain sufficient arsenic to induce chronic arsenic poisoning in man

In previous articles the normal arsenic value has been discussed and stated as not exceeding 30 micromilligrams per one hundred grams of dried specimen The earliest recognition of the ingestion of arsenic in this country probably was the work of Putnam and Hill who were able to trace the arsenic to the wall hangings In their studies 75 per cent of the specimens showed the presence of arsenic The presence of arsenic in Marine Crustaceans and Shellfish has been confirmed by Scandinavian, English, and American investigations A J Jones (1922) in the English Year Book of Pharmacy page 388 states that arsenic to the extent of 6 to 125 parts per million as arsenious oxide was found The report of the Swedish Government on the general question of arsenic poisoning is worth reading by any one interested in this subject. Sillig showed the importance of arsenic in soils, vegetables, animal foods and marine algae Endemic arsenicism has been noted in the province of Cordova in which there is an area in which both the ground and the water contain sufficient arsenic to induce chronic arsenic poisoning in man

state of affairs is largely due to lack of general knowledge of the action of these metals In the space at our disposal the subject of metals has been covered briefly and in our discussion the use of insecticides in particular is called to the attention of our readers Many known deaths and many others have yet to creep into the literature as a result of the insecticide problem In addition, the large number of subchronic symptoms accounts for many thousand other deaths In this connection attention is directed to the excellent contribution of Vogel at St. Luke's Hospital, New York, dealing with the subject of arsenic and its relation to jaundice There can be no question in regard to the widespread damage done by lead and arsenic from insecticides The damage to human health and happiness is enormous and the economic loss is beyond computation In the words of Vogel, "It is an uncanny thought to realize that this lurking poison is everywhere about us, ready to gain unsuspected entrance to our bodies from the food we eat, the water we drink and other beverages we may take to cheer us, the clothes we wear, and even the air we breath" It is as a contribution to this phase of the subject and to the possible importance of *slight degrees* of arsenic retention that the following observations are presented Thinking of metals from these points of view it may seem to present unsurmountable difficulties to those who desire to contribute to our artificial modes of living but pure, uncontaminate foods and drugs must be obtained The fixing of any limit of tolerance is and only can be relative Standards should aim at no metal at all It is only a blind effort to state that under our present mode of living some metal must be present It is further emphasized that for the most part animal experimentation will not solve the question of what constitutes harmful values because of the fact that no animal results can be translated in terms of human damage This is particularly true of the aluminum controversy

RADON AND SURGICAL DIATHERMY IN NEOPLASMS OF THE UPPER AIR PASSAGES*

By G ALLEN ROBINSON, M D, NEW YORK, N Y

SURGERY, Roentgen ray, surgical diathermy and radium are the big four therapeutic agents used in the treatment of neoplasms of the upper air passages The latter two methods have only recently been recognized as effectual and essential aids in the conquest of new growths The evolution of electrothemic methods and the romance of radon therapy are fascinating chapters in the history of medicine

The technique of surgical diathermy which includes electrodesiccation, electrocoagulation, and endotherm knife has been fully described by Clarke, Wyeth, and others and shall not be discussed in detail in this paper I should like however to advocate a correlation of the various methods used in the treatment of neoplasms rather than to argue, for example, surgery versus Roentgen ray or radon versus surgical diathermy

This paper is illustrated with lantern slides The first is a microphotograph of a squamous cell carcinoma of the tonsil, grade one, according to Broder's classification (See Figure 1) Slide two is a section taken eleven days after a surface gamma irradiation of 900 milligram hours One notices the disappearance of the squamous cell, the edema of the tissues, the infiltration of leucocytes and lymphocytes, the new formed capillaries (See Figure 2) The growth was then circumvallated with eight 10 mg platinum needles one centimeter apart for ten hours The third picture is taken six weeks later It shows the inflammatory reaction subsided and fibrous connective tissue replacing the original growth (Figure 3)

Radium needles have been supplanted largely along with bare glass seeds by implants screened with 0.2 mm of gold or platinum. The caustic beta rays are eliminated together with the subsequent painful inflammatory reaction A more accurate dosage is obtained with greater ease of application by using the filtered radon implants rather than the radium needles Careful attention should be given to the hygiene of the mouth before starting treatment Figure 4 shows the technique of inserting radon implants into the base of a carcinoma of the tonsil and tongue Each cubic centimeter of tumor tissue receives approximately one millicurie or 133 mc hrs Surface gamma radiation in amounts of 500 to 1000 mc. hrs are given either before or after the interstitial method is used This added dosage assures a greater intensity over a wider area

Primary carcinoma of the tonsil is fairly common and should be diagnosed early as patient notices slight difficulty in swallowing The lesion ulcerates early and grows rapidly The two main types are squamous cell carcinoma and the transitional cell carcinoma The latter is very radiosensitive and will disappear even under external radiation through the neck Carcinoma of the tonsil frequently extends to the soft palate, lateral wall of the pharynx or base of the tongue. The lesion should be carefully palpated to determine

*Read before the American College of Physical Therapy Chicago Ill October 9 1923

notice that the smelters are occasionally affected with a cancerous disease of the scrotum similar to that which infests chimney sweepers

Remington in this country has called attention to the presence of arsenic in American smoking and plug tobacco to the extent of 6 to 30 parts per million equivalent to 1/20 to about 1/4 grain of arsenic trioxide per pound

The present method of disposing of the boll weevil through the use of calcium arsenate puts arsenic in cotton Arsenic to the extent of 0 0973, 0 578, 0 903, and 0 109 milligrams per hundred grams has been found in cotton from four different localities It has been found in the finished cotton goods, and going a step farther patients handling these goods have shown skin manifestations Isolation of arsenic in the urine of the patients has been made
